Robust Standard Errors in Transformed Likelihood
Estimation of Dynamic Panel Data Models with
Cross-Sectional Heteroskedasticity*

November 4, 2014

Abstract

This paper extends the transformed maximum likelihood approach for estimation of dynamic panel data models by Hsiao, Pesaran, and Tahmiscioglu (2002) to the case where the errors are cross-sectionally heteroskedastic. This extension is not trivial due to the incidental parameters problem and its implications for estimation and inference. We approach the problem by working with a mis-specified homoskedastic model, and then show that the transformed maximum likelihood estimator continues to be consistent even in the presence of cross-sectional heteroskedasticity. We also obtain standard errors that are robust to cross-sectional heteroskedasticity of unknown form. By means of Monte Carlo simulations, we investigate the finite sample behavior of the transformed maximum likelihood estimator and compare it with various GMM estimators proposed in the literature. Simulation results reveal that, in terms of median absolute errors and accuracy of inference, the transformed likelihood estimator outperforms the GMM estimators in almost all cases.

Keywords: Dynamic Panels, Cross-sectional heteroskedasticity, Monte Carlo simulation, Transformed MLE, GMM estimation

*We are grateful to three anonymous referees and the Editor (Cheng Hsiao) for helpful comments and constructive suggestions. We would also like to thank participants at the 18th International Conference on Panel Data, and seminars at Osaka, Sogang and Nanyang Technological University for helpful comments. This paper was written whilst Hayakawa was visiting the University of Cambridge as a JSPS Postdoctoral Fellow for Research Abroad. He acknowledges the financial support from the JSPS Fellowship and the Grant-in-Aid for Scientific Research (KAKENHI 22730178) provided by the JSPS. Pesaran acknowledges financial support from the ESRC Grant No. ES/1031626/1. Elisa Tosetti contributed to a preliminary version of this paper. Her assistance in coding of the transformed ML estimator and some of the derivations is gratefully acknowledged.
1 Introduction

In dynamic panel data models where the time dimension \((T)\) is short, the presence of lagged dependent variables among the regressors makes standard panel estimators inconsistent, and complicates statistical inference on the model parameters considerably. To deal with these difficulties a sizable literature has emerged, starting with the seminal papers of Anderson and Hsiao (1981, 1982) who proposed the application of the instrumental variable (IV) approach to the first-differenced form of the model. More recently, a large number of studies have been focusing on the generalized method of moments (GMM), see, among others, Holtz-Eakin, Newey, and Rosen (1988), Arellano and Bond (1991), Arellano and Bover (1995), Ahn and Schmidt (1995) and Blundell and Bond (1998). One important reason for the popularity of GMM in applied economic research is that it provides asymptotically valid inference under a minimal set of statistical assumptions. Arellano and Bond (1991) proposed GMM estimators based on moment conditions where lagged variables in levels are used as instruments. Blundell and Bond (1998) showed that the performance of this estimator deteriorates when the parameter associated with the lagged dependent variable is close to unity and/or the variance ratio of the individual effects to the idiosyncratic errors is large, since in such cases the instruments are only weakly related to the lagged dependent variables.\(^1\) The poor finite sample properties of GMM estimators has been documented using Monte Carlo studies by Kiviet (2007), for example. To deal with the weak instrument problem, Arellano and Bover (1995) and Blundell and Bond (1998) proposed the use of extra moment conditions arising from the model in levels, which become available when the initial observations satisfy certain conditions. The resulting GMM estimator, known as system GMM, combines moment conditions for the model in first differences with moment conditions for the model in levels. We refer to Blundell, Bond, and Windmeijer (2000) for an extension to the multivariate case, and for a Monte Carlo study of the properties of GMM estimators using moment conditions from either the first differenced and/or levels models. More recently, Bun and Windmeijer (2010) show that the model in levels suffers from the weak instrument problem when the variance ratio is large, and Hayakawa (2007) provides finite sample evidence on the bias of the system GMM estimator for different values of the variance ratio and show that the bias rises with the variance ratio. To overcome these shortcomings, Han and Phillips (2010) and Han, Phillips, and Sul (2014) propose alternative GMM estimators.

The GMM estimators have been used in a large number of empirical studies to investigate problems in areas such as labour, development, health, macroeconomics and finance. Theoretical and applied research on dynamic panels have mostly focused on the GMM, and has by and large neglected the maximum likelihood (ML) approach though there are several theoretical advances such as Hsiao, Pesaran, and Tahmiscioglu (2002), Binder, Hsiao, and Pesaran (2005), Alvarez and Arellano (2004), and Kruiniger (2008). Hsiao, Pesaran, and Tahmiscioglu (2002) propose the transformed likelihood approach while Binder, Hsiao, and Pesaran (2005) have extended the approach to estimating panel VAR (PVAR) models. Alvarez and Arellano (2004) have studied ML estimation of autoregressive panels

\(^1\)See also the discussion in Binder, Hsiao, and Pesaran (2005), who proved that the asymptotic variance of the Arellano and Bond (1991) GMM estimator depends on the variance of the individual effects.
in the presence of time-specific heteroskedasticity (see also Bhargava and Sargan (1983)). Kruiniger (2008) considers ML estimation of a stationary/unit root AR(1) panel data models. More recently, several papers including Han and Phillips (2013), Moral-Benito (2013), Kruiniger (2013), and Juodis (2013) also consider the ML approach to estimating dynamic panel data models. There are several reasons why the GMM approach is preferred to the ML approach. First, the regularity conditions required to prove consistency and asymptotic normality of the GMM type estimators are relatively mild and allow for the presence of cross-sectional heteroskedasticity of the errors. In particular, see Arellano and Bond (1991), Arellano and Bover (1995) and Blundell and Bond (1998). Second, for the ML approach, the incidental parameters problem and the initial conditions problem lead to a violation of the standard regularity conditions, which causes inconsistency. Although Hsiao, Pesaran, and Tahmiscioglu (2002) developed a transformed likelihood approach to overcome some of the weaknesses of the GMM approach (particularly the weak IV problem), their analysis still requires the idiosyncratic errors to be homoskedastic, which is likely to be restrictive in many empirical applications.\footnote{In the application of the GMM approach to dynamic panels, it is generally difficult to avoid the so-called many/weak instruments problem, which is shown to result in biased estimates and substantially distorted test outcomes. See Section 5 for further evidence.}

It is therefore desirable to extend the transformed ML approach of Hsiao, Pesaran and Tahmiscioglu (HPT) so that it allows for heteroskedastic errors.\footnote{Note, however, that since the transformed ML approach does not impose any restrictions on the individual effects, the errors of the original panel (before differencing) can have any arbitrary degree of cross-sectional heteroskedasticity.} This is accomplished in this paper. The extension is not trivial due to the incidental parameters problem that arises, in particular its implications for inference. We follow the time series literature, and initially ignore the error variance heterogeneity and work with a mis-specified homoskedastic model, but show that the transformed maximum likelihood estimator by Hsiao, Pesaran, and Tahmiscioglu (2002) continues to be consistent. We then derive, under fairly general conditions, a covariance matrix estimator for the quasi-ML (QML) estimator which is robust to cross-sectional heteroskedasticity. Using Monte Carlo simulations, we investigate the finite sample performance of the transformed QML estimator and compare it with a range of GMM estimators. Simulation results reveal that, in terms of median absolute errors and accuracy of inference, the transformed likelihood estimator outperforms the GMM estimators in \textit{almost all cases} when the model contains an exogenous regressor, and in many cases if we consider pure autoregressive panels.

The rest of the paper is organized as follows. Section 2 describes the model and its underlying assumptions. Section 3 proposes the transformed QML estimator for cross-sectionally heteroskedastic errors. Section 4 provides an overview of the GMM estimators used in the simulation exercise. Section 5 describes the Monte Carlo design and comments on the small sample properties of the transformed likelihood and GMM estimators. Finally, Section 6 ends with some concluding remarks.
The dynamic panel data model

Consider the following dynamic panel data model

\[ y_{it} = \alpha_i + \gamma y_{it-1} + \beta x_{it} + u_{it}, \quad i = 1, 2, \ldots, N, \]  

where \( \alpha_i \), \( i = 1, 2, \ldots, N \) are the unobserved individual effects, \( u_{it} \) is an idiosyncratic error term, \( x_{it} \) is observed regressor assumed to vary over time \( t \) and across the individuals \( i \). It is further assumed that \( x_{it} \) is a scalar variable to simplify the notations.\(^4\) We refer to this model as ARX, to distinguish it from the pure autoregressive specification (AR) that does not include the exogenous regressor, \( x_{it} \). The coefficients of interest are \( \gamma \) and \( \beta \), which are assumed to be fixed finite constants. No restrictions are placed on the individual effects, \( \alpha_i \). They can be heteroskedastic, correlated with \( x_{jt} \) and \( u_{jt} \), for all \( i \) and \( j \), and can be cross-sectionally dependent. In contrast, the idiosyncratic errors, \( u_{it} \), are assumed to be uncorrelated with \( x_{it} \) for all \( i, t \) and \( t' \). However, we allow the variance of \( u_{it} \) to vary across \( i \), and let the variance ratio, \( \tau^2 = [N^{-1}\Sigma_{i=1}^{N} \text{Var}(\alpha_i)] / [N^{-1}\Sigma_{i=1}^{N} \text{Var}(u_{it})] \) to take any positive value. We shall investigate the robustness of the QML and GMM estimators to the choices of \( \tau^2 \) and \( \gamma \).

Following the literature we take first differences of (1) to eliminate the individual effects\(^5\)

\[ \Delta y_{it} = \gamma \Delta y_{i,t-1} + \beta \Delta x_{it} + \Delta u_{it}, \]  

and make the following assumptions:

**Assumption 1** (initialization) The dynamic processes (1) have started at time \( t = -m \), \( m \) being a positive constant) but only the time series data, \( \{y_{it}, x_{it}\}, (i = 1, 2, \ldots, N; t = 0, 1, \ldots, T) \), are observed.

**Assumption 2** (Exogenous variable) It is assumed that \( x_{it} \) is generated either by

\[ x_{it} = \mu_i + \phi t + \sum_{j=0}^{\infty} a_j \varepsilon_{i,t-j}, \quad \sum_{j=0}^{\infty} |a_j| < \infty \]  

or

\[ \Delta x_{it} = \phi + \sum_{j=0}^{\infty} d_j \varepsilon_{i,t-j}, \quad \sum_{j=0}^{\infty} |d_j| < \infty \]  

where \( \mu_i \) can either be fixed or random. \( \varepsilon_{it} \) are independently distributed over \( i \) and \( t \), with \( \text{E}(\varepsilon_{it}) = 0 \), and \( \text{Var}(\varepsilon_{it}) = \sigma_{\varepsilon_{it}}^2 \), where \( 0 < \sigma_{\varepsilon_{it}}^2 < K < \infty \). Also \( u_{is} \) and \( \varepsilon_{it} \) are independently distributed for all \( s \) and \( t \).

**Assumption 3** (Initialization) We suppose that either

(i) \( |\gamma| < 1 \), and the process has been going on for a long time, namely \( m \to \infty \);

\(^4\)Extension to the case of multiple regressors is straightforward at the expense of notational complexity.

\(^5\)As shown in Appendix A of Hsiao, Pesaran, and Tahmiscioglu (2002), other transformations can be used to eliminate the individual effects and the QML estimator proposed in this paper is invariant to the choice of such transformations.
or (ii) The process has started from a finite period in the past not too far back from the 0th period, namely for given values of \( y_{i,-m} \) with \( m \) finite, such that

\[
E(\Delta y_{i,-m+1}|\Delta x_{i1}, \Delta x_{i2}, \ldots, \Delta x_{iT}) = b_m + \pi'_m \Delta x_i, \text{ for all } i,
\]

where \( b_m \) is a finite constant, \( \pi_m \) is a \( T \)-dimensional vector of constants, and \( \Delta x_i = (\Delta x_{i1}, \Delta x_{i2}, \ldots, \Delta x_{iT})' \).

**Assumption 4** (idiosyncratic shocks) Disturbances \( u_{it} \) are serially and cross-sectionally independently distributed, with \( E(u_{it}) = 0 \), and \( E(u_{it}^2) = \sigma_i^2 \), such that \( 0 < \sigma_i^2 < K < \infty \), for \( i = 1, 2, \ldots, N \) and \( t = 1, 2, \ldots, T \).

**Remark 1** Assumption 3(ii) constrains the expected changes in the initial values to be the same linear functions of the observed values of the exogenous variables across all individuals. It does not require the initial values, \( y_{i,-m} \), to have the same mean across \( i \), and allows \( y_{i,-m} \) to vary both with \( i \) and \( m \). It is only required that \( y_{i,-m+1} - y_{i,-m} \) is free of the incidental parameter problem. For the relationship between Assumption 3(ii) and the initial conditions, \( y_{i,-m+1} \). See Appendix A.

**Remark 2** Assumptions 2, and 4 allow for heteroskedastic disturbances in the equations for \( y_{it} \) and \( x_{it} \).

**Remark 3** Assumption 2 requires \( x_{it} \) to be strictly exogenous. But this restriction can be relaxed by considering a panel vector autoregressive specification of the type considered in Binder, Hsiao, and Pesaran (2005). However, these further developments are beyond the scope of the present paper. See also the remarks in Section 6.

### 3 Transformed likelihood estimation

The first-differenced model (2) is well defined for \( t = 2, 3, \ldots, T \), and can be used to derive the joint distribution of \( (\Delta y_{i2}, \Delta y_{i3}, \ldots, \Delta y_{iT}) \) conditional on \( \Delta y_{i1} \). To obtain the (unconditional) distribution of \( \Delta y_{i1} \), starting from \( \Delta y_{i,-m+1} \), and by continuous substitution, we note that

\[
\Delta y_{i1} = \gamma^m \Delta y_{i,-m+1} + \beta \sum_{j=0}^{m-1} \gamma^j \Delta x_{i1-j} + \sum_{j=0}^{m-1} \gamma^j \Delta u_{i,1-j}. \tag{5}
\]

Note that the mean of \( \Delta y_{i1} \) conditional on \( \Delta y_{i,-m+1}, \Delta x_{i1}, \Delta x_{i0}, \ldots, \), is given by

\[
\eta_{i1} = E(\Delta y_{i1}|\Delta y_{i,-m+1}, \Delta x_{i1}, \Delta x_{i0}, \ldots) = \gamma^m \Delta y_{i,-m+1} + \beta \sum_{j=0}^{m-1} \gamma^j \Delta x_{i,1-j}, \tag{6}
\]

which depends on the unknown values \( \Delta y_{i,-m+1} \), and \( \Delta x_{i,1-j} \), for \( j = 1, 2, \ldots, m-1, i = 1, 2, \ldots, N \). To solve this problem, we need to express the expected value of \( \eta_{i1} \), conditional on the observables,
in a way that it only depends on a finite number of parameters. The following theorem provides the conditions under which the marginal model for $\Delta y_{i1}$ is a linear function of a finite number of unknown parameters.

**Theorem 1** Consider model (2), where $x_{it}$ follows either (3) or (4). Suppose that Assumptions 1-4 hold. Then $\Delta y_{i1}$ can be expressed as:

$$
\Delta y_{i1} = b + \pi' \Delta x_i + v_{i1},
$$

(7)

where $b$ is a constant, $\pi$ is a $T$-dimensional vector of constants, $\Delta x_i = (\Delta x_{i1}, \Delta x_{i2}, \ldots, \Delta x_{iT})'$, and $v_{i1}$ is independently distributed across $i$, such that $E(v_{i1}) = 0$, and $E(v_{i1}^2) = \omega_i \sigma_i^2$, with $0 < \omega_i < K < \infty$, for all $i$.

**Remark 4** Under Assumption 3(i) it is easily seen that $\omega_i = 2/(1 + \gamma)$. But in general $\omega_i$ need not be the same across $i$ and imposing the restrictions $\omega_i = 2/(1 + \gamma)$ might result in inconsistent estimators. On the other hand treating $\omega_i$ as a free parameter when it is in fact restricted to be the same across $i$ might lead to inefficient estimators but not inconsistent parameters, as it is shown below.

It is now possible to derive the likelihood function of the transformed model given by equations (2) for $t = 2, 3, \ldots, T$ and (7). Let $\Delta y_i = (\Delta y_{i1}, \Delta y_{i2}, \ldots, \Delta y_{iT})'$,

$$
\Delta W_i = \begin{pmatrix}
1 & \Delta x_i' & 0 & 0 \\
0 & 0 & \Delta y_{i1} & \Delta x_{i2} \\
\vdots & \vdots & \vdots & \vdots \\
0 & 0 & \Delta y_{i,T-1} & \Delta x_{iT}
\end{pmatrix},
$$

(8)

and note that the transformed model can be rewritten as

$$
\Delta y_i = \Delta W_i \varphi + r_i,
$$

(9)

with $\varphi = (b, \pi', \gamma, \beta)'$. The covariance matrix of $r_i = (v_{i1}, \Delta u_{i2}, \ldots, \Delta u_{iT})'$ has the form:

$$
E(r_i r_i') = \sigma_i^2 \Omega(\omega_i),
$$

(10)
where $\omega_i > 0$ is a free parameter defined in Theorem 1. The log-likelihood function of the transformed model (9) is given by

$$
\ell (\psi_N) = -\frac{NT}{2} \ln (2\pi) - \frac{T}{2} \sum_{i=1}^{N} \ln \sigma_i^2 - \frac{1}{2} \sum_{i=1}^{N} \ln \left[ 1 + T (\omega_i - 1) \right] \\
- \frac{1}{2} \sum_{i=1}^{N} \frac{1}{\sigma_i^2} (\Delta y_i - \Delta W_i \varphi)' \Omega (\omega_i)^{-1} (\Delta y_i - \Delta W_i \varphi),
$$

where $\psi_N = (\varphi', \omega_1, \omega_2, \ldots, \omega_N, \sigma_1^2, \sigma_2^2, \ldots, \sigma_N^2)'$.

Unfortunately, the maximum likelihood estimation based on $\ell(\psi_N)$ encounters the incidental parameters problem of Neyman and Scott (1948) since the number of parameters grows linearly with the sample size, $N$. As a way of dealing with this problem we follow the mis-specification literature in econometrics (White, 1982; Kent, 1982), and base the estimation of $\varphi$, which is finite dimensional, on a mis-specified model where the error variances are assumed (incorrectly) to be the same across $i$. We show that such quasi (pseudo) ML estimators of $\varphi$ are consistent even under the mis-specification. We then derive robust standard errors for the QMLE for use in inference. The quasi or pseudo log-likelihood function of the transformed model, (9), is given by

$$
\ell_p (\theta) = -\frac{NT}{2} \ln (2\pi) - \frac{NT}{2} \ln (\sigma^2) - \frac{N}{2} \ln \left[ 1 + T (\omega - 1) \right] \\
- \frac{1}{2\sigma^2} \sum_{i=1}^{N} (\Delta y_i - \Delta W_i \varphi)' \Omega (\omega)^{-1} (\Delta y_i - \Delta W_i \varphi),
$$

(11)

where $\theta = (\varphi', \omega, \sigma^2)'$ is the vector of unknown parameters. Let $\hat{\varphi}$ be the estimator obtained by maximizing the quasi log-likelihood function in (11), and consider the quasi-score vector

$$
\frac{\partial \ell_p (\theta)}{\partial \theta} = \begin{pmatrix}
\frac{1}{\sigma^2} \sum_{i=1}^{N} \Delta W_i' \Omega (\omega)^{-1} (\Delta y_i - \Delta W_i \varphi) \\
-\frac{NT}{2g(\omega)} + \frac{1}{2\sigma^2 g(\omega)} \sum_{i=1}^{N} r_i' r_i \\
-\frac{NT}{2\sigma^2} + \frac{1}{2\sigma^2} \sum_{i=1}^{N} r_i' \Omega (\omega)^{-1} r_i
\end{pmatrix},
$$

where $g (\omega) = |\Omega (\omega)| = 1 + T(\omega - 1)$, and

$$
\Phi = \begin{pmatrix}
T^2 & T(T - 1) & T(T - 2) & \ldots & T \\
T(T - 1) & (T - 1)^2 & (T - 1)(T - 2) & \ldots & (T - 1) \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
T & (T - 1) & (T - 2) & \ldots & 1
\end{pmatrix}.
$$

(12)
Under heteroskedastic errors, the pseudo-true value of \( \theta \) denoted by \( \theta_\ast = (\varphi'_\ast, \omega_\ast, \sigma^2_\ast)' \), is the solution of \( \lim_{N \to \infty} E [\partial \ell_p (\theta_\ast) / \partial \theta] = 0 \), namely

\[
\lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} E \left[ \Delta W'_i \Omega (\omega_\ast)^{-1} (\Delta y_i - \Delta W_i \varphi_\ast) \right] = 0,
\]

\[
- \frac{T}{2g (\omega_\ast)} + \frac{1}{2\sigma^2_\ast} \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} E \left( r'_i \Phi r_i \right) = 0,
\]

\[
- \frac{T}{2\sigma^2_\ast} + \frac{1}{2\sigma^2_\ast} \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} E \left( r'_i \Omega (\omega_\ast)^{-1} r_i \right) = 0,
\]

where expectations are taken with respect to the true probability measure.

To characterize the relationship between the true parameter values \( \varphi_{N0} = (\varphi'_0, \omega_{10}, ..., \omega_N, \sigma^2_{10}, ..., \sigma^2_{N0})' \) and the pseudo true values \( \theta_\ast = (\varphi'_\ast, \omega_\ast, \sigma^2_\ast)' \), we introduce the following average parameter measures.

**Assumption 5** The average true parameter values

\[
\sigma^2_{N0} = N^{-1} \sum_{i=1}^{N} \sigma^2_{i0}, \quad \text{and} \quad \omega_{N0} = \frac{N^{-1} \sum_{i=1}^{N} \omega_{i0} \sigma^2_{i0}}{\sum_{i=1}^{N} \sigma^2_{i0}},
\]

have finite limits (as \( N \to \infty \)) given by

\[
\sigma^2_0 = \lim_{N \to \infty} \sigma^2_{N0}, \quad \text{and} \quad \omega_0 = \frac{\lim_{N \to \infty} N^{-1} \sum_{i=1}^{N} \omega_{i0} \sigma^2_{i0}}{\lim_{N \to \infty} N^{-1} \sum_{i=1}^{N} \sigma^2_{i0}}.
\]

The above assumption is clearly satisfied if \( |\sigma_{i0}| \) and \( |\omega_{i0}| \) are finite and bounded away from zero.

The following theorem establishes the relationship between the true value and the pseudo true value.

**Theorem 2** Suppose that Assumptions 1-5 hold, and let \( \theta_\ast = (\varphi'_\ast, \omega_\ast, \sigma^2_\ast)' \) be the solution of \( \lim_{N \to \infty} E [\partial \ell_p (\theta_\ast) / \partial \theta] = 0 \), where expectations are taken with respect to the true probability measure. Then,

\[
\theta_\ast = (\varphi'_0, \omega_0, \sigma^2_0)'.
\]

The proof is provided in the appendix. This theorem summarizes one of the key results of the paper, and holds under fairly general conditions. Assumptions 1, 2, 3 are identical to those used in Hsiao et. al. (2002). Assumption 4 allows the variances of the error terms to be heteroskedastic in an unrestricted manner. Assumption 5 only requires the individual error variances and their ratios to be finite. The possible non-uniqueness of the pseudo true values in the case of heterogenous \( \omega_i \), is analogous to the non-uniqueness of the ML estimators encountered in the case of the random effect models as demonstrated initially by Maddala (1971) and further discussed by Breusch (1987) who proposes a practical approach to detecting the presence of local maxima.\(^6\) Theoretically, it is quite complicated

\(^6\)This result follows since, as established by Grassetti (2011), the transformed likelihood function can be written equivalently in the form of a random effects model with endogenous regressors. For further details see Section B.3.
to demonstrate which solution leads to the global maximum of the quasi log-likelihood function. However, the Monte Carlo simulation results in Section 5 suggest that the solution \( \theta_* = (\varphi_0', \tilde{\omega}_0, \tilde{\sigma}_0^2)' \) is associated with the global maximum. In what follows we assume that the global maximum of the probability limit of the quasi log-likelihood function is attained at \( \theta_* = (\varphi_0', \tilde{\omega}_0, \tilde{\sigma}_0^2)' = \bar{\theta}_0 \).

The following theorem establishes the asymptotic distribution of the ML estimator of the transformed model.

**Theorem 3** Suppose that Assumptions 1-5 hold and let \( \bar{\theta} = (\varphi', \tilde{\omega}, \tilde{\sigma}^2)' \) be the QML estimator obtained by maximizing the quasi (pseudo) log-likelihood function in (11). Then as \( N \) tends to infinity, \( \bar{\theta} \) is asymptotically normal with

\[
\sqrt{N} \left( \bar{\theta} - \theta_* \right) \xrightarrow{d} N \left( 0, A^*^{-1}B^*A^*-1 \right)
\]

where \( \theta_* = (\varphi_0', \tilde{\omega}_0, \tilde{\sigma}_0^2)' \),

\[
A^* = \lim_{N \to \infty} E \left[ \frac{1}{N} \frac{\partial^2 \ell_p(\theta_*)}{\partial \theta \partial \theta'} \right], \quad \text{and} \quad B^* = \lim_{N \to \infty} E \left[ \frac{1}{N} \frac{\partial \ell_p(\theta_*)}{\partial \theta} \frac{\partial \ell_p(\theta_*)}{\partial \theta'} \right],
\]

where \( \tilde{\omega}_0 \) and \( \tilde{\sigma}_0^2 \) are defined by (13).

A consistent estimator of \( A^* \), denoted by \( \hat{A}^* \) which is robust to unknown error heteroskedasticity \( (\sigma^2_{i0} + \omega_{i0} \text{ over } i) \), is given by

\[
\hat{A}^* = \begin{pmatrix}
\frac{1}{N\tilde{\sigma}^2} \sum_{i=1}^{N} \Delta W_i' \Omega(\tilde{\omega})^{-1} \Delta W_i & \frac{1}{Ng(\tilde{\omega})^2}\frac{N^2}{2\tilde{\sigma}^2} \sum_{i=1}^{N} \Delta W_i' \Phi_i \Delta W_i & 0 \\
\frac{1}{Ng(\tilde{\omega})^2}\frac{N^2}{2\tilde{\sigma}^2} \sum_{i=1}^{N} \Delta W_i' \Phi_i \Delta W_i & \frac{T^2}{2g(\tilde{\omega})^2} & \frac{T}{2\tilde{\sigma}^2} \\
0 & \frac{T}{2\tilde{\sigma}^2} & \frac{T}{2\tilde{\sigma}^4}
\end{pmatrix}
\]

where \( \Phi_i = \Delta y_i - \Delta W_i' \bar{\varphi}, \ g(\tilde{\omega}) = 1 + T(\tilde{\omega} - 1), \Phi \) is defined by (12), and \( \tilde{\sigma}^2 = N^{-1} \sum_{i=1}^{N} \tilde{r}_i' \Omega(\tilde{\omega})^{-1} \tilde{r}_i \). Partitioning \( B^* \), and its estimator \( \hat{B}^* \), accordingly to the above partitioned form of \( A^* \), we have

\[
\hat{B}_{11} = \frac{1}{N\tilde{\sigma}^4} \sum_{i=1}^{N} \Delta W_i' \Omega(\tilde{\omega})^{-1} \tilde{r}_i \tilde{r}_i' \Omega(\tilde{\omega})^{-1} \Delta W_i, \quad \hat{B}_{22} = \frac{T^2}{4g(\tilde{\omega})^4\tilde{\sigma}^4} \left\{ \frac{1}{N} \sum_{i=1}^{N} \left( \frac{\tilde{r}_i' \Phi_i \tilde{r}_i}{T} \right)^2 - g(\tilde{\omega})^2 \tilde{\sigma}^4 \right\},
\]

\[
\hat{B}_{33} = \frac{T^2}{4\tilde{\sigma}^4} \left\{ \frac{1}{N} \sum_{i=1}^{N} \left( \frac{\tilde{r}_i' \Omega(\tilde{\omega})^{-1} \tilde{r}_i}{T} \right)^2 - \tilde{\sigma}^4 \right\}, \quad \hat{B}_{21} = \frac{1}{2g(\tilde{\omega})^2\tilde{\sigma}^4} \left\{ \frac{1}{N} \sum_{i=1}^{N} \left( \tilde{r}_i' \Omega(\tilde{\omega})^{-1} \Delta W_i \right) \left( \tilde{r}_i' \Phi_i \tilde{r}_i \right) \right\},
\]

\[
\hat{B}_{31} = \frac{1}{2\tilde{\sigma}^6} \frac{1}{N} \sum_{i=1}^{N} \left( \tilde{r}_i' \Omega(\tilde{\omega})^{-1} \Delta W_i \right) \left( \tilde{r}_i' \Omega(\tilde{\omega})^{-1} \tilde{r}_i \right),
\]

\[
\hat{B}_{32} = \frac{T^2}{4g(\tilde{\omega})^2\tilde{\sigma}^4} \left\{ \frac{1}{N} \sum_{i=1}^{N} \left( \frac{\tilde{r}_i' \Phi_i \tilde{r}_i}{T} \right) \left( \frac{\tilde{r}_i' \Omega(\tilde{\omega})^{-1} \tilde{r}_i}{T} \right) - g(\tilde{\omega}) \tilde{\sigma}^4 \right\}.
\]
See also Lemma A2 and section B.4.

4 GMM Estimators: an overview

In this section, we review, and for completeness, define the GMM type estimators which are included in our simulation exercise.

The GMM approach assumes that \( \alpha_i \) and \( u_{it} \) have an error components structure,

\[
E(\alpha_i) = 0, \quad E(u_{it}) = 0, \quad E(\alpha_i u_{it}) = 0, \quad (i = 1, \ldots, N; \ t = 1, 2, \ldots, T),
\]

and the errors are uncorrelated with the initial values

\[
E(y_{i0} u_{it}) = 0, \quad (i = 1, \ldots, N; \ t = 1, 2, \ldots, T).
\]

As with the transformed likelihood approach, it is also assumed that the errors, \( u_{it} \), are serially and cross-sectionally independent:

\[
E(u_{it} u_{is}) = 0, \quad (i = 1, \ldots, N; \ t = 1, 2, \ldots, T).
\]

However, note that under the transformed QML no restrictions are placed on \( E(\alpha_i u_{it}) \), and \( E(\alpha_i u_{it}) \) are allowed to be non-zero and heterogenous across \( i \).

4.1 Estimation

4.1.1 The first-difference GMM estimator

Under (15)-(17), and focusing on the equation in first differences, (2), Arellano and Bond (1991) suggest the following \( T(T - 1)/2 \) moment conditions:

\[
E(y_{is} \Delta u_{it}) = 0, \quad (s = 0, 1, \ldots, t - 2, t = 2, 3, \ldots, T).
\]

If regressors, \( x_{it} \), are strictly exogenous, i.e., if \( E(x_{is} u_{it}) = 0 \), for all \( t \) and \( s \), then the following additional moments can also be used

\[
E(x_{is} \Delta u_{it}) = 0, \quad (s, t = 2, \ldots, T).
\]
The moment conditions (18) and (19) can be written compactly as \( E\left(\mathbf{Z}_i'\mathbf{u}_i\right) = \mathbf{0}\), where \( \mathbf{u}_i = \mathbf{q}_i - \mathbf{W}_i\mathbf{\delta}\), \( \mathbf{\delta} = (\gamma, \beta)' = (\delta_1, \delta_2)'\) and

\[
\mathbf{Z}_i = \text{diag}\left(\Delta y_{i0}, \Delta y_{i1}, \ldots, \Delta y_{iT}\right), \quad \mathbf{\dot{q}}_i = \begin{pmatrix} \Delta y_{i1} \\ \vdots \\ \Delta y_{iT} \end{pmatrix}, \quad \mathbf{W}_i = \begin{pmatrix} \Delta y_{i1} & \Delta x_{i2} \\ \vdots & \vdots \\ \Delta y_{i,T-1} & \Delta x_{iT} \end{pmatrix}.
\]

The one and two-step first-difference GMM estimators based on the above moment conditions are given by

\[
\hat{\mathbf{\delta}}_{GMM1}^{dif} = \left(\mathbf{\hat{S}}_{ZW}'\left(\hat{\mathbf{D}}_{1step}^{-1}\mathbf{\hat{S}}_{ZW}\right)^{-1}\mathbf{\hat{S}}_{ZW}'\left(\hat{\mathbf{D}}_{1step}^{-1}\mathbf{\hat{S}}_{ZW}\right)^{-1}\mathbf{\hat{S}}_{Zq}, \quad (20)
\]

\[
\hat{\mathbf{\delta}}_{GMM2}^{dif} = \left(\mathbf{\hat{S}}_{ZW}'\left(\hat{\mathbf{D}}_{2step}^{-1}\mathbf{\hat{S}}_{ZW}\right)^{-1}\mathbf{\hat{S}}_{ZW}'\left(\hat{\mathbf{D}}_{2step}^{-1}\mathbf{\hat{S}}_{ZW}\right)^{-1}\mathbf{\hat{S}}_{Zq},
\]

where \( \mathbf{\hat{S}}_{ZW} = \frac{1}{N}\sum_{i=1}^{N} \mathbf{\hat{Z}}_i'\mathbf{\hat{W}}_i, \mathbf{\hat{S}}_{Zq} = \frac{1}{N}\sum_{i=1}^{N} \mathbf{\hat{Z}}_i'\mathbf{\hat{q}}_i, \mathbf{\hat{D}}_{1step} = \frac{1}{N}\sum_{i=1}^{N} \mathbf{\hat{Z}}_i'\mathbf{H}\mathbf{\hat{Z}}_i, \mathbf{\hat{D}}_{2step} = \frac{1}{N}\sum_{i=1}^{N} \mathbf{\hat{Z}}_i'\mathbf{\hat{u}}_i'\mathbf{\hat{u}}_i'\mathbf{\hat{Z}}_i, \mathbf{\hat{u}}_i = \mathbf{\hat{q}}_i - \mathbf{\hat{W}}_i\mathbf{\hat{\delta}}_{GMM1}^{dif}, \) and \( \mathbf{H} \) is a matrix with 2's on the main diagonal, -1's on the first upper and lower sub-diagonals and 0's elsewhere.

### 4.1.2 System GMM estimator

Although consistency of the first-difference GMM estimator is obtained under the no serial correlation assumption, Blundell and Bond (1998) demonstrated that it suffers from the so-called weak instruments problem when \( \gamma \) is close to unity, and/or the variance ratio \( \tau^2 = \frac{\Sigma_{i=1}^{N} var(\alpha_i)}{\Sigma_{i=1}^{N} var(u_{it})} \) is large. As a solution, these authors propose the system GMM estimator due to Arellano and Bover (1995) and show that it works well even if \( \gamma \) is close to unity. But as shown recently by Bun and Windmeijer (2010), the system GMM estimator continues to suffer from the weak instruments problem when the variance ratio, \( \tau^2 \) is large. See also Appendix of Binder, Hsiao, and Pesaran (2005) where it is shown that the asymptotic variance of the GMM estimator is an increasing function of \( \tau^2 \).

To introduce the moment conditions for the system GMM estimator, we need to assume \( E(y_{it}\alpha_i) = E(y_{it}\alpha_i) \) and \( E(x_{is}\alpha_i) = E(x_{is}\alpha_i) \), for all \( s \) and \( t \). Under these assumptions, we have the following moment conditions:

\[
E[\Delta y_{is}\left(\alpha_i + u_{it}\right)] = 0, \quad (s = 1, \ldots, t - 1, t = 2, 3, \ldots, T), \quad (21)
\]

\[
E[\Delta x_{is}\left(\alpha_i + u_{it}\right)] = 0, \quad (s, t = 2, 3, \ldots, T). \quad (22)
\]

In setting up the moment conditions for the system GMM estimator, given the moment conditions for the first-difference GMM estimator, some of the moment conditions in (21) and (22) are redundant. Hence, to implement the system GMM estimation, in addition to (18) and (19), we use the following.
moment conditions:

\[ E[\Delta y_{i,t-1} (\alpha_i + u_{it})] = 0, \quad (t = 2, 3, \ldots, T), \]  
\[ E[\Delta x_{it} (\alpha_i + u_{it})] = 0, \quad (t = 2, 3, \ldots, T). \]  

The moment conditions (18), (19), (23) and (24) can be written compactly as \( E(\tilde{Z}_i^t \tilde{u}_i) = 0 \), where \( \tilde{u}_i = \tilde{q}_i - \tilde{W}_i \delta, \)\(^7\)

\[ \tilde{Z}_i = \text{diag} (\tilde{Z}_i, \tilde{Z}_i), \quad \tilde{Z}_i = \text{diag} [(\Delta y_{i1}, \Delta x_{i2}), (\Delta y_{i2}, \Delta x_{i3}), \ldots, (\Delta y_{i,T-1}, \Delta x_{iT})], \]

\[ \tilde{q}_i = \begin{pmatrix} q_i \\ \vdots \\ q_i \end{pmatrix}, \quad \tilde{q}_i = \begin{pmatrix} y_{i1} \\ \vdots \\ y_{iT} \end{pmatrix}, \quad \tilde{W}_i = \begin{pmatrix} W_i \\ \vdots \\ W_i \end{pmatrix}, \quad \tilde{W}_i = \begin{pmatrix} y_{i1} & x_{i2} \\ \vdots & \vdots \\ y_{i,T-1} & x_{iT} \end{pmatrix}. \]

The one and two-step system GMM estimators based on the above moment conditions are given by

\[ \hat{\delta}_{GMM1}^{\text{sys}} = \left( \tilde{S}_{ZW} \left( \tilde{D}_{1\text{step}} \right)^{-1} \tilde{S}_{ZW} \right)^{-1} \tilde{S}_{ZW} \left( \tilde{D}_{1\text{step}} \right)^{-1} \tilde{S}_{Zq}, \] \[ \hat{\delta}_{GMM2}^{\text{sys}} = \left( \tilde{S}_{ZW} \left( \tilde{D}_{2\text{step}} \right)^{-1} \tilde{S}_{ZW} \right)^{-1} \tilde{S}_{ZW} \left( \tilde{D}_{2\text{step}} \right)^{-1} \tilde{S}_{Zq}, \]

where \( \tilde{S}_{ZW} = \frac{1}{N} \sum_{i=1}^{N} \tilde{Z}_i^t \tilde{W}_i \), \( \tilde{S}_{Zq} = \frac{1}{N} \sum_{i=1}^{N} \tilde{Z}_i^t \tilde{q}_i \) and \( \tilde{D}_{1\text{step}} = \text{diag} \left( \frac{1}{N} \sum_{i=1}^{N} \tilde{Z}_i^t \tilde{H} \tilde{Z}_i, \frac{1}{N} \sum_{i=1}^{N} \tilde{Z}_i^t \tilde{q}_i \right) \).

The two-step system GMM estimator is obtained by replacing \( \tilde{D}_{1\text{step}} \) with \( \tilde{D}_{2\text{step}} = \frac{1}{N} \sum_{i=1}^{N} \tilde{Z}_i^t \tilde{u}_i \tilde{Z}_i, \)

where \( \tilde{u}_i = \tilde{q}_i - \tilde{W}_i \hat{\delta}_{GMM1}^{\text{sys}} \).

### 4.1.3 Continuous-updating GMM estimator

Since the two-step GMM estimators tend to perform poorly in small samples, (Newey and Smith, 2004), alternative estimation methods have been proposed in the literature. These include the empirical likelihood estimator, (Qin and Lawless, 1994), the exponential tilting estimator (Kitamura and Stutzer, 1997; Imbens, Spady, and Johnson, 1998) and the continuous updating (CU-) GMM estimator (Hansen, Heaton, and Yaron, 1996), where these are members of the generalized empirical likelihood estimator (Newey and Smith, 2004). Amongst these estimators, we focus on the CU-GMM estimator as an alternative to the two-step GMM estimator.

To define the CU-GMM estimator, we need some additional notation. Let \( \tilde{Z}_i \) denote \( \tilde{Z}_i \) or \( \tilde{Z}_i \), and \( \tilde{u}_i \) denote \( \tilde{u}_i \) or \( \tilde{u}_i \), and set

\[ g_i(\delta) = Z_i^t \tilde{u}_i, \quad \tilde{g}_N(\delta) = \frac{1}{N} \sum_{i=1}^{N} g_i(\delta), \]

\(^7\)Although additional moment conditions proposed by Ahn and Schmidt (1995) could be used, we mainly focus on the above two set of moment conditions since they are often used in applied research.
\[ \hat{\Omega}_N(\delta) = \frac{1}{N} \sum_{i=1}^{N} [g_i(\delta) - \tilde{g}_N(\delta)] [g_i(\delta) - \tilde{g}_N(\delta)]'. \] (28)

Then, the CU-GMM estimator is defined as

\[ \hat{\delta}_{GMM-CU} = \arg \min_{\delta} \tilde{g}_N(\delta) \hat{\Omega}_N(\delta)^{-1} \tilde{g}_N(\delta). \] (29)

Newey and Smith (2004) demonstrate that the CU-GMM estimator has a smaller finite sample bias than the two-step GMM estimator.

4.2 Inference using GMM estimators

4.2.1 Alternative standard errors

In the case of GMM estimators the choice of the covariance matrix is often as important as the choice of the estimator itself for inference. Although, it is clearly important that the estimator of the covariance matrix should be consistent, in practice it might not have favorable finite sample properties and could result in inaccurate inference. To address this problem a number of modified standard errors have been proposed. For the two-step GMM estimators, Windmeijer (2005) proposes corrected standard errors for linear static panel data models which are applied to dynamic panel models by Bond and Windmeijer (2005). For the CU-GMM, while it is asymptotically equivalent to the two-step GMM estimator, it is more dispersed than the two-step GMM estimator in finite samples and inference based on conventional standard errors formula results in large size distortions. To overcome this problem, Newey and Windmeijer (2009) propose an alternative estimator for the covariance matrix of CU-GMM estimator under many-weak moments asymptotics and demonstrate by simulation that the use of the modified standard errors improve the size property of the tests based on the CU-GMM estimators.

4.2.2 Weak instruments robust inference

As noted above, the first-difference and system GMM estimators could be subject to the weak instruments problem, which in turn could lead to biased estimates and invalid inferences. To overcome the weak instrument problem a number of tests have been proposed in the literature that have the correct size asymptotically regardless of the strength of instruments. These include Stock and Wright (2000) and Kleibergen (2005). Stock and Wright (2000) propose a GMM version of the Anderson and Rubin (AR) test (Anderson and Rubin, 1949). Kleibergen (2005) proposes a Lagrange Multiplier (LM) test. This author also extends the conditional likelihood ratio (CLR) test of Moreira (2003) to the GMM case since the CLR test performs better than other tests in linear homoskedastic regression models.

We now introduce tests of this type which we include in the Monte Carlo (MC) experiments to be reported next. The GMM version of the AR statistic proposed by Stock and Wright (2000) is given
by
\[ \mathcal{AR}(\delta) = 2NQ_N(\delta), \]  
(30)
where \( Q_N(\delta) = \hat{g}_N(\delta)'\hat{\Omega}(\delta)^{-1}\hat{g}_N(\delta)/2 \), and \( \hat{g}_N(\delta) \) is defined by (27). Under the null hypothesis \( H_0 : \delta = \delta_0 \), \( \mathcal{AR}(\delta_0) \) is asymptotically distributed as \( \chi^2_n \), as \( N \to \infty \), regardless of the strength of the instruments, where \( n \) is the dimension of \( \hat{g}_N(\delta_0) \).

The LM statistic proposed by Kleibergen (2005) is
\[ LM(\delta) = N\frac{\partial Q_N(\delta)}{\partial \delta'} \left[ \hat{D}(\delta)'\hat{\Omega}(\delta)^{-1}\hat{D}(\delta) \right]^{-1} \frac{\partial Q_N(\delta)}{\partial \delta}, \]  
(31)
where \( \hat{D}(\delta) = (\hat{d}_1(\delta), \hat{d}_2(\delta)) \) with
\[ \hat{d}_j(\delta) = \frac{1}{N} \sum_{i=1}^N \frac{\partial g_i(\delta)}{\partial \delta_j} - \left( \frac{1}{N} \sum_{i=1}^N \frac{\partial g_i(\delta)}{\partial \delta_j} \right) \hat{\Omega}(\delta)^{-1} \hat{g}_N(\delta), \quad \text{for } j = 1, 2. \]
Under the null hypothesis \( H_0 : \delta = \delta_0 \), \( LM(\delta_0) \) is asymptotically distributed as \( \chi^2_k \), where \( k \) is the dimension of \( \delta \), which is equal to 2 in our application.

The GMM version of the CLR statistic proposed by Kleibergen (2005) is given by
\[ CLR(\delta) = \frac{1}{2} \left[ \mathcal{AR}(\delta) - \hat{R}(\delta) + \sqrt{\left( \mathcal{AR}(\delta) - \hat{R}(\delta) \right)^2 + 4LM(\delta)\hat{R}(\delta)} \right], \]  
(32)
where \( \hat{R}(\delta) \) is a statistic which is large when instruments are strong and small when the instruments are weak, and is random only through \( \hat{D}(\delta) \) asymptotically. In the MC simulations, following Newey and Windmeijer (2009), we use \( \hat{R}(\delta) = N \cdot \lambda_{\min} \left( \hat{D}(\delta)'\hat{\Omega}(\delta)^{-1}\hat{D}(\delta) \right) \) where \( \lambda_{\min}(A) \) denotes the smallest eigenvalue of \( A \). Under the null hypothesis \( H_0 : \delta = \delta_0 \), this statistic has a nonstandard distribution whose critical values can be obtained by simulation.\(^8\)

5 Monte Carlo simulations

In this section, we conduct Monte Carlo simulations to investigate the finite sample properties of the transformed QML approach and compare them to those of the various GMM estimators proposed in the literature and reviewed in the previous section.

5.1 Panel ARX(1) model

We first consider a panel distributed lag model with one exogenous regressor, panel ARX(1), which is likely to be more relevant in practice than the pure panel AR(1) model which will be considered later.

\(^8\)For further details see Kleibergen (2005) and Newey and Windmeijer (2009).
5.1.1 Monte Carlo design

For each $i$, the time series processes $\{y_{it}\}$ are generated as

$$y_{it} = \alpha_i + \gamma y_{i,t-1} + \beta x_{it} + u_{it}, \quad \text{for } t = -m + 1, -m + 2, \ldots, 0, 1, \ldots, T,$$

where $u_{it} \sim \mathcal{N}(0, \sigma_i^2)$, with $\sigma_i^2 \sim \mathcal{U}[0.5, 1.5]$, so that $E(\sigma_i^2) = 1$. For the initial values, we set $y_{i,-m} = 0$ and note that for $m$ sufficiently large,

$$y_{i0} \approx \left(\frac{1 - \gamma^m}{1 - \gamma}\right) \alpha_i + \beta \sum_{j=0}^{m-1} \gamma^j x_{i,-j} + \sum_{j=0}^{m-1} \gamma^j u_{i,-j}.$$

We discard the first $m = 50$ observations, and use the observations $t = 0$ through $T$ for estimation and inference.\(^9\) The regressor, $x_{it}$, is generated as

$$x_{it} = \mu_i + \zeta_{it}, \quad \text{for } t = -m, -m + 1, \ldots, 0, 1, \ldots, T,$$

where $\mu_i \sim \text{iid}\mathcal{N}(0, 1)$

$$\zeta_{it} = \phi \zeta_{i,t-1} + \varepsilon_{it}, \quad \text{for } t = -49, -48, \ldots, 0, 1, \ldots, T,$$

$$\varepsilon_{it} \sim \mathcal{N}(0, \sigma_{\varepsilon i}^2), \quad \zeta_{i,-50} = 0.$$

with $|\phi| < 1$. We also generate a set of heteroskedastic errors for the $x_{it}$ process and generate $\sigma_{\varepsilon i}^2 \sim \mathcal{U}[0.5, 1.5]$, independently of $\sigma_i^2$, which ensures that the variance ratio $\sigma_i^2/\sigma_{\varepsilon i}^2$ is also heteroscedastic across $i$. We discard the first 50 observations of $\zeta_{it}$ and use the remaining $T + 1 + m$ observations for generating $x_{it}$ and $y_{it}$.

In the simulations, we try the values $\gamma = 0.0, 0.4, 0.9$, and $\phi = 0.5$. The slope coefficient, $\beta$, is chosen to ensure a reasonable degree of fit. But to deal with the error variance heterogeneity across the different equations in the panel we use the following average measure of fit

$$R_{y}^2 = 1 - \frac{N^{-1} \sum_{i=1}^{N} \text{Var}(u_{it})}{N^{-1} \sum_{i=1}^{N} \text{Var}(y_{it}|c_i)},$$

where $\text{Var}(y_{it}|c_i)$ is the time-series variation of $i^{th}$ unit. Since $y_{it}$ is stable and it is assumed to have started some time in the past we have

$$y_{it} = c_i + \beta \sum_{j=0}^{\infty} \gamma^j \zeta_{i,t-j} + \sum_{j=0}^{\infty} \gamma^j u_{i,t-j} = c_i + \beta w_{it} + \sum_{j=0}^{\infty} \gamma^j u_{i,t-j},$$

$$c_i = (\alpha_i + \beta \mu_i) / (1 - \gamma), \text{ and } w_{it} \text{ is an AR(2) process, } w_{it} = \varphi_1 w_{i,t-1} + \varphi_2 w_{i,t-2} + \varepsilon_{it}, \text{ with parameters}$$

---

\(^9\)Hence, $T + 1$ is the actual length of the estimation sample.
\[ \varphi_1 = \gamma + \phi, \varphi_2 = -\phi \gamma, \text{ and having the variance (Hamilton, 1994, p. 58)} \]

\[ \text{Var}(w_i) = \frac{(1 + \phi \gamma) \sigma_i^2}{(1 - \phi \gamma)(1 + \phi \gamma)^2 - (\gamma + \phi)^2} = \frac{(1 + \phi \gamma) \sigma_i^2}{(1 - \gamma^2)(1 - \phi^2)(1 - \phi \gamma)}. \]

Hence

\[ R_y^2 = 1 - \frac{N^{-1} \sum_{i=1}^{N} \sigma_i^2 - \beta^2(1 + \phi \gamma) N^{-1} \sum_{i=1}^{N} \sigma_i^2}{(1 - \gamma^2)(1 - \phi^2)(1 - \phi \gamma)} + \frac{N^{-1} \sum_{i=1}^{N} \sigma_i^2}{(1 - \gamma^2)(1 - \phi^2)(1 - \phi \gamma)} = \frac{\beta^2(1 + \phi \gamma) \sigma_N^2}{(1 - \phi^2)(1 - \phi \gamma)} + \gamma^2 \sigma_N^2, \]

\[ \sigma_N^2 = N^{-1} \sum_{i=1}^{N} \sigma_i^2, \text{ and } \sigma_{\varepsilon N}^2 = N^{-1} \sum_{i=1}^{N} \sigma_{\varepsilon i}^2. \]

For \( N \) sufficiently large we now have (note that \( \sigma_N^2 \) and \( \sigma_{\varepsilon N}^2 \to 1 \) with \( N \to \infty \))

\[ R_y^2 = \frac{1}{1 - R_y^2} \left( \frac{\beta^2(1 + \phi \gamma)}{(1 - \phi^2)(1 - \phi \gamma)} + \gamma^2 \right) + 1, \]

and

\[ \beta^2 = \left( \frac{R_y^2 - \gamma^2}{R_y^2} \right) \frac{1}{1 - R_y^2} \left( \frac{(1 - \phi^2)(1 - \phi \gamma)}{(1 + \phi \gamma)} \right). \]

We set \( \beta \) such that \( R_y^2 = \gamma^2 + 0.1 \). For \( \gamma = 0.0, \gamma = 0.4 \) and \( \gamma = 0.9 \), we have \( R_y^2 = 0.1, R_y^2 = 0.26 \) and \( R_y^2 = 0.91 \), respectively.

For the individual effects, we set

\[ \alpha_i = \eta (\mu_i + \tilde{u}_i + v_i), \]

where \( \tilde{u}_i = T^{-1} \sum_{t=1}^{T} u_{it} \), and \( v_i \sim iid \mathcal{N}(0,1) \). To set \( \eta \) we consider the variance ratio,

\[ \tau^2 = \frac{N^{-1} \sum_{i=1}^{N} \text{Var}(\alpha_i)}{N^{-1} \sum_{i=1}^{N} \text{Var}(u_{it})} \frac{\text{Var}(\alpha_i) \eta^2 (T^{-1} \sigma_N^2 + 2)}{\sigma_N^2}, \]

and use two values for \( \tau^2 \), namely a low value of \( \tau^2 = 1 \) often set in the Monte Carlo experiments conducted in the literature, and the high value of \( \tau^2 = 5 \). The sample sizes considered are \( N = 50, 150, 500 \) and \( T = 5, 10, 15 \).

For the computation of the transformed QML estimators, we try two procedures. One is to maximize the log likelihood function directly, while the other is to use an iterative procedure suggested by Grassetti (2011). For the starting value of the nonlinear optimization, we use the minimum distance estimator of Hsiao, Pesaran, and Tahmiscioğlu (2002) where \( \omega \) is estimated by the one-step first-
difference GMM estimator (20) in which $\hat{\mathbf{Z}}_i$ is replaced with

$$
\hat{\mathbf{Z}}_i = \begin{pmatrix}
y_{i0} & x_{i1} & 0 & 0 
y_{i1} & x_{i2} & y_{i0} & x_{i1} 
\vdots & \vdots & \vdots & \vdots 
y_{i,T-2} & x_{i,T-1} & y_{i,T-3} & x_{i,T-2}
\end{pmatrix}.
$$

This GMM estimator is also used as the starting value for the iterative procedure.

For the GMM estimators, although there are many moment conditions for the first-difference GMM estimator as in (18) and (19), we consider three sets of moment conditions which only exploit a sub-set of the available instruments. The first set of moment conditions, denoted as “DIF1”, consists of $E(y_{is}\Delta u_{it}) = 0$ for $s = 0, \ldots, t - 2$; $t = 2, \ldots, T$ and $E(x_{is}\Delta u_{it}) = 0$ for $s = 1, \ldots, t$; $t = 2, \ldots, T$. In this case, the number of moment conditions are 24, 99, 224 for $T = 5, 10, 15$, respectively. The second set of moment conditions, denoted as “DIF2”, consists of $E(y_{it-l-1}\Delta u_{it}) = 0$ with $l = 0$ for $t = 2$, $l = 0, 1$ for $t = 3, \ldots, T$ and $E(x_{it-l-1}\Delta u_{it}) = 0$ with $l = 0, 1$ for $t = 2$, $l = 0, 1, 2$ for $t = 3, \ldots, T$. In this case, the number of moment conditions are 18, 43, 68 for $T = 5, 10, 15$, respectively. The third set of moment conditions, denoted as “DIF3”, consists of $\sum_{t=2}^{T} E(y_{it-2}\Delta u_{it}) = 0$, $\sum_{t=2}^{T} E(x_{it}\Delta u_{it}) = 0$, and $\sum_{t=2}^{T-1} E(x_{it}\Delta u_{it}) = 0$. The number of moment conditions for this case, often called the stacked instruments, are 4 for all $T$. Similarly, for the system GMM estimator, we add moment conditions (23) and (24) in addition to “DIF1” and “DIF2”, which are denoted as “SYS1” and “SYS2”, respectively. For “SYS1” we have 32, 117 and 252 moment conditions for $T = 5, 10$, and 15, respectively, while for “SYS2” we have 26, 61, and 96 moment conditions for $T = 5, 10$, and 15, respectively. Also, we add moment conditions $\sum_{t=2}^{T} E[\Delta y_{it-1}(\alpha_i + u_{it})] = 0$, $\sum_{t=2}^{T-1} E[\Delta y_{it-1}(\alpha_i + u_{it})] = 0$, $\sum_{t=2}^{T} E[\Delta x_{it}(\alpha_i + u_{it})] = 0$, and $\sum_{t=2}^{T-1} E[\Delta x_{it}(\alpha_i + u_{it})] = 0$ in addition to “DIF3”, which is denoted as “SYS3”. In this case, the number of moment conditions is 8 for any $T$.

In a number of cases where $N$ is not sufficiently large relative to the number of moment conditions (for example, when $T = 15$ and $N = 50$) the inverse of the weighting matrix can not be computed. Such cases are denoted by “-” in the summary result tables.

For inference, we use the robust standard errors formula given in Theorem 2 for the transformed QML estimator. For the GMM estimators, in addition to the conventional standard errors, we also compute Windmeijer (2005)’s standard errors with finite sample correction for the two-step GMM estimators and Newey and Windmeijer (2009)’s alternative standard errors formula for the CU-GMM estimators. For the computation of optimal weighting matrix, a centered version is used except for the CU-GMM.\footnote{In the earlier version, we used centered weighting matrix. However, in this version, uncentered weighting matrix is used for the CU-GMM since it gave better performance than using centered weighting matrix.}

In addition to the Monte Carlo results for $\gamma$ and $\beta$, we also report simulation results for the long-run coefficient defined by $\psi = \beta/(1 - \gamma)$. We report median bias, median absolute errors (MAE), size
and power for $\gamma$, $\beta$ and $\psi$. The power is computed at $\gamma - 0.1$, $\beta - 0.1$ and $(\beta - 0.1)/(1 - (\gamma - 0.1))$, for selected null values of $\gamma$ and $\beta$. All tests are carried out at the 5% significance level, and all experiments are replicated 1,000 times.

5.1.2 MC results for panel ARX(1) model

To save space, we report the results of the transformed QMLE and GMM estimators which exploit moment conditions “DIF2” and “SYS2” with one-step estimation procedure for $\gamma = 0.4, 0.9$ only. The reason for selecting these moment conditions is that, in practice, these moment conditions are often used to mitigate the finite sample bias caused by using too many instruments. A complete set of results giving the remaining GMM estimators that make use of additional instruments are provided in a supplement available from the authors on request.

The small sample results for $\gamma$ and $\beta$ are summarized in Tables 1 to 4. We first focus on the results of $\gamma$ and then discuss the results for $\beta$. Since the results for $\gamma = 0.0$ and $\gamma = 0.4$ are very similar, we focus on the case of $\gamma = 0.4$. Table 1 (and A.12 in the supplement) provide the results of bias and MAE for the case of $\gamma = 0.4$, and shows that the transformed QMLE has a smaller bias than the GMM estimators in all cases with the exception of the CU-GMM estimator (see Table A.12). In terms of MAE the transformed QMLE outperforms the GMM estimators in all cases.

As for the effect of increasing the variance ratio, $\tau^2$, on the various estimators, we first recall that the transformed QMLE is invariant to the choice of $\tau^2$. In contrast, as to be expected the performance of the GMM estimators deteriorates (in some case substantially) as $\tau^2$ is increased from 1 to 5. This tendency is especially evident in the case of the system GMM estimators, and is in sharp contrast to the performance of the transformed QMLE which is robust to changes in $\tau^2$. These observations also hold if we consider the experiments with $\gamma = 0.9$ (Table 2). Although the GMM estimators have smaller biases than the transformed likelihood estimator in a few cases, in terms of MAE, the transformed QMLE performs best in all cases (see also Table A.22 in the supplement).

We next consider size and power of the various tests, summarized in Tables 3 and 4 (A.3, A.13 and A.23 in the supplement). The results in these tables show that the empirical size of the transformed QMLE is close to the nominal size of 5% for all values of $\gamma, T$, $N$ and $\tau^2$. In contrast, for the GMM estimators, we find that the test sizes vary considerably depending on $\gamma, T$, $N$, $\tau^2$, the estimation method (1step, 2step, CU), and whether corrections are applied to the standard errors. In the case of the GMM results without standard error corrections, most of the GMM methods are subject to substantial size distortions when $N$ is small. For instance, when $\gamma = 0.4$, $N = 50$, $T = 5$, and $\tau^2 = 1$, the size of the test based on the two-step procedure using moment conditions “DIF2” estimator is 34.2%. But the size distortion gets smaller as $N$ increases. Increasing $N$ to 500, reduces the size of this test to 7.7%. However, even with $N = 500$, the size distortion gets larger for two-step and CU-GMM estimators as $T$ increases.

As to the effects of changes in $\tau^2$ on the estimators, we find that the system GMM estimators are

---

11 The corresponding tables in the supplement are labelled as Tables A.1 to A.30.
significantly affected when $\tau^2$ is increased. When $\tau^2 = 5$, all the system GMM estimators have large size distortions even when $T = 5$ and $N = 500$, where conventional asymptotics are expected to work well. This may be due to large finite sample biases caused by a large $\tau^2$.

For the tests based on corrected GMM standard errors, Windmeijer (2005)’s correction seems to be quite useful, and in many cases it leads to accurate inference, although the corrections do not seem able to mitigate the size problem of the system GMM estimator when $\tau^2$ is large. The standard errors of Newey and Windmeijer (2009) are also helpful: they improve the size property in many cases.

Comparing power of the tests, we observe that the transformed likelihood estimator is in general more powerful than the GMM estimators. Specifically, the transformed likelihood estimators have higher power than the most efficient two-step system GMM estimator based on “SYS1” with Windmeijer’s correction.

The above conclusions for size and power hold generally when we consider experiments with $\gamma = 0.9$ (Table 4 and A.23), except that the system GMM estimators now perform rather poorly even for a relatively large $N$. For example, when $\gamma = 0.9$, $T = 5$, $N = 500$ and $\tau^2 = 1$, size distortions of the system GMM estimators are substantial, as compared to the case where $\gamma = 0.4$. Although it is known that the system GMM estimators break down when $\tau^2$ is large\(^\text{12}\), the simulation results in Table 4 and A.23 reveal that they perform poorly even when $\tau^2$ is not so large ($\tau^2 = 1$).

We next consider the small sample results for $\gamma$ (Tables 1 to 4, A.14 to A.16, and A.24 to A.26). The outcomes are similar to the results reported for $\gamma$. The transformed likelihood estimator tends to have smaller biases and MAEs than the GMM estimators in many cases, and there are almost no size distortions for all values of $T$, $N$ and $\tau^2$. The performance of the GMM estimators crucially depends on the values of $T$, $N$ and $\tau^2$. Unless $N$ is large, the GMM estimators perform poorly and the system GMM estimators are subject to substantial size distortions when $\tau^2$ is large even for $N = 500$, although the magnitude of size distortions are somewhat smaller than those reported for $\gamma$.

The results for the long-run coefficient, $\psi = \beta/(1 - \gamma)$, which are reported in the supplement (Tables A.7 to A.9, A.17 to A.19 and A.27 to A.29), are very similar to those of $\gamma$ and $\beta$. Although the GMM estimators outperform the transformed likelihood estimator in some cases, in terms of MAE, the transformed likelihood estimator performs best in almost all cases. As for inference, the transformed likelihood estimator has correct sizes for all values of $T$, $N$ and $\tau^2$ when $\gamma = 0.4$. However, it shows some size distortions when $\gamma = 0.9$ and the sample size is small, say, when $T = 5$ and $N = 50$. However, size improves as $T$ and/or $N$ increase(s). When $T = 15$ and $N = 500$, there is essentially no size distortions. For the GMM estimators, it is observed that although the sizes are correct in some cases, say, the case with $T = 5$ and $N = 500$ when $\gamma = 0.4$, it is not the case when $\gamma = 0.9$; even for the case of $T = 5$ and $N = 500$, there are size distortions and a large $\tau^2$ aggravates the size distortions.

Finally, we consider weak instruments robust tests, which are reported in Table 5, and Tables A.10, A.20 and A.30 of the supplement. We find that test sizes are close to the nominal value only when $T = 5$ and $N = 500$. In other cases, especially when $N$ is small and/or $T$ is large, there are substantial

\(^{12}\text{See Hayakawa (2007) and Bun and Windmeijer (2010).}\)
size distortions. Although Newey and Windmeijer (2009) prove the validity of these tests under many weak moments asymptotics, they are essentially imposing \( n^2/N \to 0 \) where \( n \) is the number of moment conditions, which is unlikely to hold when \( N \) is small and/or \( T \) is large. Therefore, the weak instruments robust tests are less appealing, considering the very satisfactory size properties of the transformed likelihood estimator, the difficulty of carrying out inference on subset of the parameters using the weak instruments robust tests, and large size distortions observed for these tests when \( N \) is small.

In summary, for estimation of ARX panel data models the transformed likelihood estimator has several favorable properties over the GMM estimators in that the transformed likelihood estimator generally performs better than the GMM estimators in terms of biases, MAEs, size and power, and unlike GMM estimators, it is not affected by the variance ratio, \( \tau^2 \).

5.2 Panel AR(1) model

5.2.1 Monte Carlo design

The data generating process is the same as that in the previous section with \( \beta = 0 \). More specifically, \( y_{it} \) are generated as

\[
y_{it} = \alpha_i + \gamma y_{i,t-1} + u_{it}, \quad (t = -m + 1, \ldots, 1, \ldots, T; i = 1, \ldots, N),
\]

with \( y_{i,-m} = 0 \), where \( u_{it} \sim \mathcal{N}(0, \sigma_i^2) \), \( \sigma_i^2 \sim \mathcal{U}[0.5, 1.5] \), and

\[
y_{i0} \approx \left( \frac{1 - \gamma^m}{1 - \gamma} \right) \alpha_i + \sum_{j=0}^{m-1} \gamma^j u_{i,-j}.
\]

Individual effects are generated as

\[
\alpha_i = \eta (\bar{u}_i + v_i),
\]

where \( v_i \sim iid\mathcal{N}(0, 1) \), and \( \eta \) is set so that to control the variance ratio

\[
\tau^2 = \frac{N^{-1} \sum_{i=1}^{N} Var(\alpha_i)}{N^{-1} \sum_{i=1}^{N} Var(u_{it})} = \frac{\eta^2 (T^{-1} \sigma_N^2 + 1)}{\sigma_N^2}.
\]

Note that for \( N \) sufficiently large \( \tau^2 \approx \eta^2(1 + 1/T) \). For parameters and sample sizes, we consider \( \gamma = 0.0, 0.4, 0.9, \) \( T = 5, 10, 15, 20 \) \( N = 50, 150, 500 \), and \( \tau^2 = 1, 5 \).

Some comments on the computations are in order. In the nonlinear optimization routine for the computation of the QMLE we use \((\tilde{b}, \tilde{\gamma}, \tilde{\omega}, \tilde{\sigma}^2)\) as starting values, where \( \tilde{b} = N^{-1} \sum_{i=1}^{N} \Delta y_{i1} \), \( \tilde{\gamma} \) is the
one-step first-difference GMM estimator (20) where \( \hat{W}_t \) and \( \hat{Z}_t \) are replaced with\(^{13}\)

\[
\hat{W}_t = \begin{pmatrix}
\Delta y_{t1} \\
\vdots \\
\Delta y_{t,T-1}
\end{pmatrix}, \quad \hat{Z}_t = \begin{pmatrix}
y_{t0} & 0 & 0 \\
y_{t1} & y_{t0} & 0 \\
y_{t2} & y_{t1} & y_{t0} \\
\vdots & \vdots & \vdots \\
y_{t,T-2} & y_{t,T-3} & y_{t,T-4}
\end{pmatrix},
\]

\( \tilde{\omega} = [(N-1)\tilde{\sigma}_u^2]^{-1} \sum_{i=1}^{N} (\Delta y_{i1} - \bar{b})^2 \) and \( \tilde{\sigma}_u^2 = [2N(T-2)]^{-1} \sum_{i=1}^{N} (\Delta y_{it} - \bar{\gamma}\Delta y_{i,t-1})^2 \).

For the first-difference GMM estimators, we consider three sets of moment conditions. The first set of moment conditions, denoted as “DIF1”, consists of \( E(y_{its} \Delta u_{it}) = 0 \) for \( s = 0, \ldots, t - 2; t = 2, \ldots, T \). In this case, the number of moment conditions are 10, 45, 105, and 190 for \( T = 5, 10, 15, \) and 20, respectively. The second set of moment conditions, denoted by “DIF2”, consist of \( E(y_{i,t-2} \Delta u_{it}) = 0 \) with \( l = 0 \) for \( t = 2 \), and \( l = 0, 1 \) for \( t = 3, \ldots, T \). In this case, the number of moment conditions are 7, 17, 27, and 37 for \( T = 5, 10, 15, \) and 20, respectively. The third set of moment conditions, denoted as “DIF3”, consists of \( \sum_{t=2}^{T} E(y_{i,t-2} \Delta u_{it}) = 0 \) and \( \sum_{t=2}^{T-1} E(y_{i,t-2} \Delta u_{it}) = 0 \) and \( \sum_{t=2}^{T-2} E(y_{i,t-2} \Delta u_{it}) = 0 \). In this case, the number of moment conditions are 3 for all \( T \).

Similarly, for the system GMM estimator, we add moment conditions \( E[\Delta y_{i,t-1}(\alpha_i + u_{it})] = 0 \) for \( t = 2, \ldots, T \) in addition to “DIF1” and “DIF2”, which are denoted as “SYS1” and “SYS2”, respectively. We also add moment conditions \( \sum_{t=2}^{T} E[\Delta y_{i,t-1}(\alpha_i + u_{it})] = 0 \), \( \sum_{t=2}^{T-1} E[\Delta y_{i,t-1}(\alpha_i + u_{it})] = 0 \), \( \sum_{t=2}^{T} E[\Delta x_{it}(\alpha_i + u_{it})] = 0 \) and \( \sum_{t=2}^{T-1} E[\Delta x_{it}(\alpha_i + u_{it})] = 0 \) in addition to “DIF3”. For the moment conditions “SYS1”, we have 14, 54, 119, and 209 moment conditions for \( T = 5, 10, 15, \) and 20, respectively, while for the moment conditions “SYS2”, we have 11, 26, 41, and 56 moment conditions for \( T = 5, 10, 15, \) and 20, respectively. The number of moment conditions for “SYS3” are 6 for all \( T \). With regard to the inference, we use the robust standard errors formula given in Theorem 2 for the transformed log-likelihood estimator. For the GMM estimators, in addition to the conventional standard errors, we also compute Windmeijer (2005)’s standard errors for the two-step GMM estimators and Newey and Windmeijer (2009)’s standard errors for the CU-GMM estimators.

We report the median bias, median absolute errors (MAE), sizes (\( \gamma = 0.0, 0.4 \) and 0.9) and powers (resp. \( \gamma = -0.1, 0.3 \) and 0.8) with the nominal size set to 5%. As before, the number of replications is set to 1,000.

5.2.2 MC results for panel AR(1) model

As with the ARX(1) experiments, to save space, we report the results of the transformed likelihood estimator and the GMM estimators exploiting moment conditions “DIF2” and “SYS2” with one-step estimation procedure for \( \gamma = 0.4, \) and 0.9. A complete set of results are provided in a supplement, \(^{13}\)This type of estimator is considered in Bun and Kiviet (2006). Since the number of moment conditions are three, this estimator is always computable for any values of \( N \) and \( T \) considered in this paper. Also, since there are two more moments, we can expect that the first and second moments of the estimator to exist.
which is available upon request. In the following, Tables 6 to 8 are given in the paper and Tables A.31 to A.42 are given in the supplement.

The bias and MAEs of the various estimators for the case of $\gamma = 0.4$ are summarized in Table 6, and Tables A.32, A.36 and A.40 of the supplement. As can be seen from these tables, the transformed likelihood estimator performs best (in terms of MAE) in almost all cases, the exceptions being the CU-GMM estimators that show smaller biases in some experiments. As to be expected, the one- and two-step GMM estimators deteriorate as the variance ratio, $\tau^2$, is increased from 1 to 5, and this tendency is especially evident for the system GMM estimator. For the case of $\gamma = 0.9$, we find that the system GMM estimators have smaller biases and MAEs than the transformed likelihood estimator in some cases. However, when $\tau = 5$, the transformed likelihood estimator outperforms the GMM estimators in all cases, both in terms of bias and MAE.

Consider now the size and power properties of the alternative procedures. The results for $\gamma = 0.4$ are summarized in Table 7 and Table A.37 of the supplement. We first note that the transformed likelihood procedure has the correct size for all experiments. For the GMM estimators, although there are substantial size distortions when $N = 50$, the empirical sizes become close to the nominal value as $N$ is increased. When $T = 5$ or 10 and $N = 500$ and $\tau^2 = 1$, the size distortion of the GMM estimators are small. However, when $\tau^2 = 5$, there are severe size distortions for the system GMM estimator even when $N = 500$. Also similar results to the ARX(1) case are obtained when the tests are based on modified standard errors. For example, Windmeijer (2005)'s correction is quite useful, and in many cases it leads to accurate inference although the corrections do result in severely under-sized tests in some cases. Also, this correction does not seem that helpful in mitigating the size problem of the system GMM estimator when $\tau^2$ is large. The standard errors of Newey and Windmeijer (2009) used for the CU-GMM estimators are also helpful - they tend to improve the size property in many cases.

Size and power of the tests in the case of experiments with $\gamma = 0.9$ are summarized in Table 7 and Table A.41 of the supplement, and show significant size distortions in many cases. The size distortion of the transformed likelihood gets reduced for relatively large sample sizes and its size declines to 8.0% when $\tau^2 = 1$, $N = 500$ and $T = 20$. As to be expected, increasing the variance ratio, $\tau^2$, to 5, does not change this result. A similar pattern can also be seen in the case of first-difference GMM estimators if we consider $\tau^2 = 1$. But the size results are much less encouraging if we consider the system GMM estimators. Also, as to be expected, size distortion of GMM type estimators become much more pronounced when the variance ratio is increased to $\tau^2 = 5$.

Finally, we consider the small sample performance of the weak instruments robust tests which are provided in Table 8, and Tables A.34, A.38 and A.42 of the supplement. These results show that size distortions are reduced only when $N$ is large ($N = 500$). In general, size distortions of these tests

---

14In the case of QMLE procedure, one reason for the size distortion is the closeness of $\gamma$ to the boundary value of 1. In the computation of $\hat{\gamma}_{QML}$, the parameter space for $\gamma$ is restricted to $|\gamma| \leq 0.999$. However, when the sample sizes $N$ and $T$ are small, there are cases where $\hat{\gamma}_{QML}$ exceeds unity, but in that case, $\hat{\gamma}_{QML}$ is set to the boundary value of 0.999. This could also introduce some bias in the standard errors. The case where $\gamma = 1$ requires a different MC design and its investigation is beyond the scope of the present paper.
get worse as $T$, or the number of moment conditions, increases. In terms of power, the Lagrange multiplier test and conditional likelihood ratio test based on “SYS2” have almost the same power as the transformed likelihood estimator when $\gamma = 0.4$, $T = 5$, $N = 500$ and $\tau^2 = 1$. For the case of $\gamma = 0.9$, the results are very similar to the case of $\gamma = 0.4$. Size distortions are small only when $N$ is large. When $N$ is small, there are substantial size distortions.

6 Concluding remarks

In this paper we consider the transformed likelihood approach to estimation and inference in dynamic panel data models with cross-sectionally heteroskedastic errors, and shown that the transformed likelihood estimator due to Hsiao, Pesaran, and Tahmiscioglu (2002) continues to be consistent and asymptotically normally distributed, but the covariance matrix of the transformed likelihood estimators must be adjusted to allow for the cross-sectional heteroskedasticity. By means of Monte Carlo simulations, we investigated the finite sample performance of the transformed likelihood estimator and compared it with a range of GMM estimators. Simulation results revealed that the transformed likelihood estimator for an ARX(1) model with a single exogenous regressor has very small biases and yields test sizes that are close to nominal values, and in most cases outperform the GMM estimators, whose small sample properties vary considerably across parameter values ($\gamma$ and $\beta$), the choice of the moment conditions, and the value of the variance ratio, $\tau^2$.

In this paper, $x_{it}$ is assumed to be strictly exogenous. However, in practice, the regressors may be endogenous or weakly exogenous (c.f. Keane and Runkle, 1992). To allow for endogenous and weakly exogenous variables, one could consider extending the panel VAR approach advanced in Binder, Hsiao, and Pesaran (2005) to allow for cross-sectional heteroskedasticity. More specifically, consider the following bivariate model:

$$
\begin{align*}
\begin{bmatrix}
y_{it} \\
x_{it}
\end{bmatrix}
&= \begin{bmatrix}
\alpha_{yi} + \gamma y_{i,t-1} + \beta x_{it} + u_{it} \\
\alpha_{xi} + \phi y_{i,t-1} + \rho x_{i,t-1} + v_{it}
\end{bmatrix}
\end{align*}
$$

where $\text{cov}(u_{it}, v_{it}) = \theta$. In this model, $x_{it}$ is strictly exogenous if $\phi = 0$ and $\theta = 0$, weakly exogenous if $\theta = 0$, and endogenous if $\theta \neq 0$. This model can be written as a PVAR(1) model as follows

$$
\begin{pmatrix}
y_{it} \\
x_{it}
\end{pmatrix}
= \begin{pmatrix}
\alpha_{yi} + \beta \alpha_{xi} \\
\alpha_{xi}
\end{pmatrix}
+ \begin{pmatrix}
\gamma + \beta \phi & \beta \rho \\
\phi & \rho
\end{pmatrix}
\begin{pmatrix}
y_{i,t-1} \\
x_{i,t-1}
\end{pmatrix}
+ \begin{pmatrix}
u_{it} + \beta v_{it} \\
v_{it}
\end{pmatrix},
$$

for $i = 1, 2, ..., N$. Let $A = \{a_{ij}\}(i, j = 1, 2)$ be the coefficient matrix of $(y_{i,t-1}, x_{i,t-1})'$ in the above VAR model. Then, we have $\beta = a_{12}/a_{22}$, $\gamma = a_{11} - a_{12}a_{21}/a_{22}$, $\rho = a_{22}$ and $\phi = a_{21}$. Thus, if we estimate a PVAR model in $(y_{it}, x_{it})$, allowing for fixed effects and cross-sectional heteroskedasticity, we can recover the parameters of interest, $\gamma$ and $\beta$, from the estimated coefficients of the PVAR model. However, detailed analysis of such a model is beyond the scope of the present paper and is left to

23
future research.

A Remark 1: Interpretation of initial conditions

In Remark 1, we noted that $y_{i,-m}$ can vary freely across $i$ so long as the means and variances of $\Delta y_{i,-m+1}$ are free from the incidental parameter problem, and hence $y_{i0}$ does not need to follow a stationary distribution. As an illustration consider the following data generating process:

$$
y_{it} = \alpha_i + \gamma y_{i,t-1} + \beta x_{it} + u_{it}, \quad (t = -m + 1, \ldots, 0, 1, \ldots, T)$$
$$y_{i,-m} = \frac{\delta y_1}{1 - \gamma} \alpha_i + \left(\frac{\delta y_2 + \delta y_1}{1 - \gamma}\right) \mu_i + \bar{u}_{i,-m},$$
$$x_{it} = \eta_i + \rho x_{i,t-1} + \epsilon_{it}, \quad (t = -m + 1, \ldots, 0, 1, \ldots, T)$$
$$x_{i,-m} = \frac{\delta x_1}{1 - \gamma} \alpha_i + \left(\frac{\delta x_2 + \delta x_1}{1 - \gamma}\right) \mu_i + \bar{\epsilon}_{i,-m},$$

where $\mu_i = \eta_i / (1 - \rho)$ and $|\rho| < 1$. For simplicity, we do not include a time trend in the $x_{it}$ process. However, the results do not change as long as the coefficient of time trend is homogenous across $i$.

The above system can be written as a VAR(1) model:

$$w_{it} = \lambda_i + A w_{i,t-1} + v_{it}, \quad (t = -m + 1, -m + 2, \ldots, T),$$
$$w_{i,-m} = D (I - A)^{-1} \lambda_i + \tilde{v}_{i,-m}$$

where $I_2$ is a $2 \times 2$ identity matrix, $w_{it} = (y_{it}, x_{it})'$, $\lambda_i = (\alpha_i + \beta \eta_i, \eta_i)'$, $v_{it} = (u_{it} + \beta \epsilon_{it}, \epsilon_{it})'$, $\tilde{v}_{i,-m} = (\tilde{u}_{i,-m}, \tilde{\epsilon}_{i,-m})'$,

$$A = \begin{pmatrix} \gamma & \beta \\ 0 & \rho \end{pmatrix}, \quad D = \begin{pmatrix} \delta y_1 & \delta y_2 \\ \delta x_1 & \delta x_2 \end{pmatrix}, \quad (I - A)^{-1} \lambda_i = \begin{pmatrix} \frac{\alpha_i + \beta \eta_i}{1 - \gamma} \\ \mu_i \end{pmatrix}.$$

Note that $w_{it}$ can be written as

$$w_{it} = A^{t+m} w_{i,-m} + (I_2 - A^{t+m}) (I_2 - A)^{-1} \lambda_i + \sum_{j=0}^{t+m-1} A^j v_{i,t-j}$$
$$= [I_2 - A^{t+m} (I_2 - D)] \begin{pmatrix} \frac{\alpha_i + \beta \eta_i}{1 - \gamma} \\ \mu_i \end{pmatrix} + \sum_{j=0}^{t+m-1} A^j v_{i,t-j} + A^{t+m} \tilde{v}_{i,-m}.$$
After some algebra, we have the following explicit expressions for \( y_{it} \) and \( x_{it} \):

\[
 y_{it} = \left[ 1 - \gamma^{t+m} (1 - \delta_{y1}) + A_{12}^{t+m} \delta_{x1} \right] \frac{\alpha_i + \beta \mu_i}{(1 - \gamma)} + \left[ \gamma^{t+m} \delta_{y2} - A_{12}^{t+m} (1 - \delta_{x2}) \right] \mu_i \\
+ \sum_{j=0}^{t+m-1} \left[ \gamma^j (u_{i,t-j} + \beta \varepsilon_{i,t-j}) + A_{12}^j \varepsilon_{i,t-j} \right] + \gamma^{t+m} \tilde{u}_{i,-m} + A_{12}^{t+m} \tilde{\varepsilon}_{i,-m},
\]

and

\[
 x_{it} = \rho^{t+m} \delta_{x1} \left( \frac{\alpha_i}{1 - \gamma} \right) + \left[ 1 + \frac{\rho^{t+m} \beta \delta_{x1}}{(1 - \gamma)} - \rho^{t+m} (1 - \delta_{x2}) \right] \mu_i + \sum_{j=0}^{t+m-1} \rho^j \varepsilon_{i,t-j} + \rho^{t+m} \tilde{\varepsilon}_{i,-m} \\
= h_{\alpha,t} \alpha_i + h_{\mu,t} \mu_i + \zeta_{it}.
\]

where \( \tilde{\varepsilon}_{i,-m} = \sum_{j=0}^{\infty} \rho^j \varepsilon_{i,-j} \), and \( A_{12}^j \) is the \((1, 2)\) element of \( A^j \). Note that when \( \delta_{x1} = 0 \), \( \delta_{x2} = 1 \) then \( x_{it} \) satisfies Assumption 2. However, the specification of \( \tilde{\varepsilon}_{i,-m} \) is not essential for the following results to hold. \( \tilde{\varepsilon}_{i,-m} \) can be any arbitrary random variable as long as it is independently distributed of \( u_{it} \) and has a finite second order moment. The conditional expectations of \( y_{it} \) and \( x_{it} \) given individual effects can be written as

\[
\begin{pmatrix}
 E(y_{it}|\alpha_i, \mu_i) \\
 E(x_{it}|\alpha_i, \mu_i)
\end{pmatrix} = \begin{pmatrix}
 [1 - \gamma^{t+m} (1 - \delta_{y1}) + A_{12}^{t+m} \delta_{x1}] \frac{\alpha_i + \beta \mu_i}{(1 - \gamma)} + \left[ \gamma^{t+m} \delta_{y2} - A_{12}^{t+m} (1 - \delta_{x2}) \right] \mu_i \\
\rho^{t+m} \delta_{x1} \left( \frac{\alpha_i}{1 - \gamma} \right) + \left[ 1 + \frac{\rho^{t+m} \beta \delta_{x1}}{(1 - \gamma)} - \rho^{t+m} (1 - \delta_{x2}) \right] \mu_i
\end{pmatrix}.
\]

From this expression, we find that \( E(y_{it}|\alpha_i, \mu_i) \) does not depend on \( t \) only when \( \delta_{y1} = \delta_{x2} = 1 \) and \( \delta_{y2} = \delta_{x1} = 0 \), and that \( E(x_{it}|\alpha_i, \mu_i) \) does not depend on \( t \) when \( \delta_{x2} = 1 \) and \( \delta_{x1} = 0 \) for any \( \delta_{y1} \) and \( \delta_{y2} \). With these restrictions we now investigate the validity of Assumption 3.(ii). Using

\[
\Delta y_{i,-m+1} = \alpha_i + (\gamma - 1) y_{i,-m} + \beta x_{i,-m+1} + u_{i,-m+1} \\
= \left[ (1 - \delta_{y1}) + \frac{\beta \rho}{(1 - \gamma)} \delta_{x1} \right] \alpha_i + \left[ (1 - \delta_{y1}) \beta - (1 - \gamma) \delta_{y2} + \frac{\rho \beta^2}{(1 - \gamma)} \delta_{x1} - \rho \beta (1 - \delta_{x2}) \right] \mu_i \\
+ \beta (\varepsilon_{i,-m+1} + \rho \varepsilon_{i,-m}) + u_{i,-m+1} - (1 - \gamma) \tilde{u}_{i,-m}
\]

we have

\[
E(\Delta y_{i,-m+1}|\Delta x_i) = \left[ (1 - \delta_{y1}) + \frac{\beta \rho}{(1 - \gamma)} \delta_{x1} \right] E(\alpha_i|\Delta x_i) \\
+ \left[ (1 - \delta_{y1}) \beta - (1 - \gamma) \delta_{y2} + \frac{\rho \beta^2}{(1 - \gamma)} \delta_{x1} - \rho \beta (1 - \delta_{x2}) \right] E(\mu_i|\Delta x_i) \\
+ \beta E(\varepsilon_{i,-m+1} + \rho \varepsilon_{i,-m}|\Delta x_i).
\]

This expression suggests that the validity of Assumption 3.(ii) depends on the stochastic properties of \( \alpha_i \) and \( \mu_i \), and the initial conditions. To investigate the situations under which Assumption 3.(ii)
holds, we provide some preliminary results. First, note that

$$\Delta x_i = \Delta h_{\alpha} \alpha_i + \Delta h_{\mu} \mu_i + \Delta \zeta_i,$$

where $h_{\alpha} = (h_{\alpha,1}, h_{\alpha,2}, ..., h_{\alpha,T})'$, $h_{\mu} = (h_{\mu,1}, h_{\mu,2}, ..., h_{\mu,T})'$ and $\zeta_i = (\zeta_{i1}, \zeta_{i2}, ..., \zeta_{iT})'$. Also under the assumption that $E(\alpha_i) = \alpha$ and $E(\mu_i) = \mu$, we have

$$E(\varepsilon_{i,-m+1} + \rho \tilde{\varepsilon}_{i,-m} | \Delta x_i) = \pi'_{\varepsilon,i} \Delta x_i, \quad \pi_{\varepsilon,i} = var(\Delta x_i)^{-1} cov(\Delta x_i, \varepsilon_{i,-m+1} + \rho \tilde{\varepsilon}_{i,-m}),$$

$$E(\alpha_i | \Delta x_i) = \alpha + \pi'_{\alpha,i} \Delta x_i, \quad \pi_{\alpha,i} = var(\Delta x_i)^{-1} cov(\Delta x_i, \alpha_i),$$

$$E(\mu_i | \Delta x_i) = \mu + \pi'_{\mu,i} \Delta x_i, \quad \pi_{\mu,i} = var(\Delta x_i)^{-1} cov(\Delta x_i, \mu_i)$$

where (note that $\Delta h_{\alpha}$ and $\Delta h_{\mu}$ are non-stochastic constants)

$$var(\Delta x_i) = var(\alpha_i) \Delta h_{\alpha} \Delta h'_{\alpha} + var(\mu_i) \Delta h_{\mu} \Delta h'_{\mu} + cov(\alpha_i, \mu_i) \left[ \Delta h_{\alpha} \Delta h'_{\mu} + \Delta h_{\mu} \Delta h'_{\alpha} \right] + \sigma^2_{\varepsilon i} Q,$$

$$cov(\Delta x_i, \varepsilon_{i,-m+1} + \rho \tilde{\varepsilon}_{i,-m}) = E[\Delta \zeta_i (\varepsilon_{i,-m+1} + \rho \tilde{\varepsilon}_{i,-m})] = \sigma^2_{\varepsilon i} Q,$$

$$cov(\Delta x_i, \alpha_i) = \Delta h_{\alpha} var(\alpha_i) + \Delta h_{\mu} cov(\alpha_i, \mu_i),$$

$$cov(\Delta x_i, \mu_i) = \Delta h_{\alpha} cov(\alpha_i, \mu_i) + \Delta h_{\mu} var(\mu_i),$$

and $E(\Delta \zeta_i \Delta \zeta'_i) = \sigma^2_{\varepsilon i} Q$. Consider now Case I when $\delta_{y_1} = \delta_{x_2} = 1$ and $\delta_{y_2} = \delta_{x_1} = 0$ i.e., $D = I_2$. We do not need to impose any assumptions on $\alpha_i$ and $\mu_i$, and hence, $\alpha_i$ and $\mu_i$ can be either fixed or random. (Case II) When $\delta_{x_1} = 0$, $\delta_{x_2} = 1$, and $\alpha_i$ and $\mu_i$ are random with homogenous means, Assumption 3.(ii) is valid for any $\delta_{y_1}$ and $\delta_{y_2}$ since $\Delta x_i = \Delta \zeta_i$, $\pi_{\varepsilon,i}$, $\pi_{\alpha,i}$ and $\pi_{\mu,i}$ are all homogenous over $i$. (Case III) When $\delta_{x_1} \neq 0$ and/or $\delta_{x_2} \neq 1$, and $\alpha_i$ and $\mu_i$ are random with homogenous means, then Assumption 3.(ii) is valid when the ratios $cov(\mu_i, \alpha_i) / \sigma^2_{\varepsilon i}$, $var(\alpha_i) / \sigma^2_{\varepsilon i}$ and $var(\mu_i) / \sigma^2_{\varepsilon i}$ are homogenous over $i$. Thus, there is a trade-off between the assumptions made on the fixed effects and the initial conditions.

## B Mathematical proofs

### B.1 Preliminary results

In this appendix we provide some definitions and results useful for the derivations in the paper. First, from (B.2) of Hsiao, Pesaran, and Tahmiscioglu (2002), the inverse of $\Omega(\omega)$ defined in (10) is given
by

$$\Omega^{-1}(\omega) = g(\omega)^{-1} \begin{pmatrix} T & T - 1 & \ldots & 2 & 1 \\ T - 1 & (T - 1)\omega & \ldots & 2\omega & \omega \\ T - 2 & 2\omega & \ldots & 2[(T - 2)\omega - (T - 3)] & (T - 2)\omega - (T - 3) \\ 2 & \omega & \ldots & (T - 2)\omega - (T - 3) & (T - 1)\omega - (T - 2) \\ 1 & \omega & \ldots & \omega & \omega \end{pmatrix}.$$  

where $g(\omega)$ is defined above (12). The generic $(t, s)$th element of the $(T - 1) \times (T - 1)$ lower block of $\Omega^{-1}(\omega)$, denoted by $\tilde{\Omega}(\omega)$, can be calculated using the following formulae, for $t, s = 1, 2, \ldots, T - 1$:

$$\left\{ \tilde{\Omega}(\omega) \right\}_{ts} = \begin{cases} s(T - t)\omega - (s - 1)(T - t), & (s \leq t) \\ t(T - s)\omega - (t - 1)(T - s), & (s > t) \end{cases}.$$  

(33)

Next, using the fact that $\Phi$, defined in (12), can be written as $\Phi = \vartheta \vartheta'$, where $\vartheta' = (T, T - 1, \ldots, 2, 1)$, (Hsiao, Pesaran, and Tahmiscioglu, 2002, p.144), we have

$$\text{tr}(\Phi \Omega(\omega)) = \text{tr} (\vartheta \vartheta' \Omega(\omega)) = \vartheta' \Omega(\omega) \vartheta = Tg(\omega) = T[1 + T(\omega - 1)].$$

**Lemma A1** Consider the transformed model (9). Under Assumptions 1-5, we have

$$\lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} E \left[ \Delta W_{i} \Omega(\bar{\omega}_{0})^{-1} r_{i} \right] = 0,$$  

(34)

where $\Omega(\omega)$ is given in (10), $\bar{\omega}_{0}$ is defined in (12). Further,

$$\lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} E (\Delta W_{i} \Phi r_{i}) = \left( \begin{array}{c} 0 \\ 0'_{T \times 1} \tilde{\delta} \quad 0 \end{array} \right)'$$  

(35)

where $\Phi$, and $\tilde{\delta}$ are given by (12) and (39), respectively.

**Proof.** Let $p_{i} = \Omega(\bar{\omega}_{0})^{-1} r_{i} = (p_{i1}, \ldots, p_{iT})'$ and recall that $r_{i} = (v_{i1}, \Delta u_{i2}, \ldots, \Delta u_{iT})'$. Hence, using (33) we have

$$p_{i1} = Tv_{i1} + \sum_{s=2}^{T} (T - s + 1)\Delta u_{is},$$

$$p_{it} = (T - t + 1)v_{i1} + \sum_{s=2}^{t} h_{ts}(\bar{\omega}_{0}) \Delta u_{is} + \sum_{s=t+1}^{T} k_{ts}(\bar{\omega}_{0}) \Delta u_{is}, \quad (t = 2, \ldots, T - 1)$$

$$p_{iT} = v_{i1} + \sum_{s=2}^{T} h_{Ts}(\bar{\omega}_{0}) \Delta u_{is}$$

27
and
\[
\begin{align*}
h_{ts}(\tilde{w}_0) &= (T - t + 1) [(s - 1)\tilde{w}_0 - (s - 2)], \\
k_{ts}(\tilde{w}_0) &= (T - s + 1) [(t - 1)\tilde{w}_0 - (t - 2)].
\end{align*}
\]

Also using (8) and Assumption 2, it readily follows that
\[
E \left[ \Delta \mathbf{W}'_t \Omega (\tilde{w}_0)^{-1} \mathbf{r}_i \right] = E \left( \Delta \mathbf{W}'_t \mathbf{p}_i \right) = [0, 0, \ldots, E \left( \Delta \tilde{y}'_{i-1} \mathbf{p}_i \right), 0]',
\]
where $\Delta \tilde{y}_{i-1} = (0, \Delta y_{i1}, \ldots, \Delta y_{i,T-1})'$. Hence to establish (34) we need to prove that
\[
\lim_{N \to \infty} N^{-1} \sum_{i=1}^N E \left( \Delta \tilde{y}'_{i-1} \mathbf{p}_i \right) = 0.
\]

But, noting that $E(\Delta u_{is}\Delta y_{it}) = 0$ for $t < s - 1$, we have
\[
E \left( \Delta \tilde{y}'_{i-1} \mathbf{p}_i \right) = \sum_{t=2}^T E \left( p_{it}\Delta y_{i,t-1} \right) = \sum_{t=2}^{T-1} E \left( p_{it}\Delta y_{i,t-1} \right) + E \left( p_{iT}\Delta y_{i,T-1} \right)
\]
\[
= \sum_{t=2}^{T-1} E \left[ (T - t + 1)v_{i1}\Delta y_{i,t-1} + \sum_{s=2}^t h_{ts}(\tilde{w}_0)\Delta u_{is}\Delta y_{i,t-1} + \sum_{s=t+1}^T k_{ts}(\tilde{w}_0)\Delta u_{is}\Delta y_{i,t-1} \right]
\]
\[
+ E \left( p_{iT}\Delta y_{i,T-1} \right)
\]
\[
= \sum_{t=2}^T (T - t + 1)E \left( v_{i1}\Delta y_{i,t-1} \right) + \sum_{t=2}^T \sum_{s=2}^t h_{ts}(\tilde{w}_0)E \left( \Delta u_{is}\Delta y_{i,t-1} \right)
\]
\[
= A_{1i} + A_{2i}(\tilde{w}_0).
\]

Also, we have\(^1\)
\[
E(v_{i1}\Delta y_{it}) = \begin{cases} 
\sigma_i^2 \omega_{i0} & t = 1 \\
\sigma_i^2 \gamma^{t-2}(\gamma \omega_{i0} - 1) & t = 2, \ldots, T
\end{cases}
\]
\[
E(\Delta u_{is}\Delta y_{it}) = \begin{cases} 
-\sigma_i^2 & t = s - 1 \\
\sigma_i^2(2 - \gamma) & s = t \\
-\sigma_i^2(1 - \gamma)^{t-s-1} & s < t
\end{cases}.
\]

\(^1\)These results are obtained by noting that $\Delta y_{it}$ can be written as follows
\[
\Delta y_{i1} = b + \pi'\Delta x_i + v_{i1},
\]
\[
\Delta y_{it} = \gamma^{t-1} \Delta y_{i1} + \beta \left( \sum_{j=0}^{t-2} \gamma^j x_{i,t-j} \right) + \sum_{j=0}^{t-2} \gamma^j \Delta u_{i,t-j}
\]
\[
= \gamma^{t-1} (b + \pi'\Delta x_i) + \gamma^{t-1} v_{i1} + \beta \left( \sum_{j=0}^{t-2} \gamma^j x_{i,t-j} \right) + \sum_{j=0}^{t-2} \gamma^j \Delta u_{i,t-j}, \quad (t = 2, \ldots, T).
\]
Using these results we now have 

\[ A_{1i} = \sigma_{i0}^2 \left[ (T - 1) \omega_{i0} + (\gamma \omega_{i0} - 1) \sum_{t=3}^{T} (T - t + 1) \gamma^{t-3} \right] \]

\[ = \sigma_{i0}^2 \left[ (T - 1) \omega_{i0} + \frac{(\gamma \omega_{i0} - 1) ((T + \gamma - T \gamma - 2) + \gamma^{T-1})}{(1 - \gamma)^2} \right], \]

and (recalling that \( h_{ts} \) depends on \( \tilde{\omega}_0 \))

\[ A_{2i} = \tilde{h}_{22} (\tilde{\omega}_0) E(\Delta u_{i2} \Delta y_{i1}) \]

\[ + \tilde{h}_{32} (\tilde{\omega}_0) E(\Delta u_{i2} \Delta y_{i2}) + \tilde{h}_{33} (\tilde{\omega}_0) E(\Delta u_{i3} \Delta y_{i2}) \]

\[ + \tilde{h}_{42} (\tilde{\omega}_0) E(\Delta u_{i2} \Delta y_{i3}) + \tilde{h}_{43} (\tilde{\omega}_0) E(\Delta u_{i3} \Delta y_{i3}) + \tilde{h}_{44} (\tilde{\omega}_0) E(\Delta u_{i4} \Delta y_{i3}) \]

\[ + \tilde{h}_{52} (\tilde{\omega}_0) E(\Delta u_{i2} \Delta y_{i4}) + \tilde{h}_{53} (\tilde{\omega}_0) E(\Delta u_{i3} \Delta y_{i4}) + \tilde{h}_{54} (\tilde{\omega}_0) E(\Delta u_{i4} \Delta y_{i4}) + \tilde{h}_{55} (\tilde{\omega}_0) E(\Delta u_{i5} \Delta y_{i4}) \]

\[ : \]

\[ + \tilde{h}_{T2} (\tilde{\omega}_0) E(\Delta u_{i2} \Delta y_{i,T-1}) + \tilde{h}_{T3} (\tilde{\omega}_0) E(\Delta u_{i3} \Delta y_{i,T-1}) + \cdots + \tilde{h}_{T,T-2} (\tilde{\omega}_0) E(\Delta u_{i,T-2} \Delta y_{i,T-1}) + \]

\[ + \tilde{h}_{T,T-1} (\tilde{\omega}_0) E(\Delta u_{i,T-1} \Delta y_{i,T-1}) + \tilde{h}_{TT} (\tilde{\omega}_0) E(\Delta u_{iT} \Delta y_{i,T-1}) \]

\[ = \sigma_{i0}^2 \left[ (-1) \sum_{s=2}^{T} h_{ss} (\tilde{\omega}_0) + (2 - \gamma) \sum_{s=2}^{T-1} h_{s+1,s} (\tilde{\omega}_0) - (1 - \gamma)^2 \sum_{t=4}^{T} \sum_{s=2}^{t-2} h_{ts} (\tilde{\omega}_0) \gamma^{t-s-2} \right] \]

\[ = A_{2i}^{(1)} (\tilde{\omega}_0) + A_{2i}^{(2)} (\tilde{\omega}_0) + A_{2i}^{(3)} (\tilde{\omega}_0). \]

Then, by using (36), we have

\[ A_{2i}^{(1)} (\tilde{\omega}_0) = \sigma_{i0}^2 \left[ (-1) \sum_{s=2}^{T} (T - s + 1) ((s - 1) \tilde{\omega}_0 - (s - 2)) \right] \]

\[ = \sigma_{i0}^2 \left[ 3T - \omega_0 - T \omega_0 + \frac{1}{6} (T + 1) (T + 2) (T + 3 \omega_0 - T \omega_0 - 6) + 2 \right] \]

\[ A_{2i}^{(2)} (\tilde{\omega}_0) = \sigma_{i0}^2 \left[ (2 - \gamma) \sum_{s=2}^{T-1} (T - s) ((s - 1) \tilde{\omega}_0 - (s - 2)) \right] \]

\[ = -\frac{\sigma_{i0}^2}{6} (\gamma - 2) (T - 1) (T - 2) (-T + T \omega_0 + 3) \]

29
\[
A_{2i}^{(3)}(\bar{w}_0) = \sigma_0^2 \left[ -(1 - \gamma)^2 \sum_{t=4}^{T} \sum_{s=2}^{t-2} \gamma^{t-s-2} (T - t + 1) ((s - 1) \bar{w}_0 - (s - 2)) \right] \\
= -\sigma_0^2 \left( -10T + 2\gamma + 2\bar{w}_0 + 6T\gamma + 6T\bar{w}_0 - 4\gamma\bar{w}_0 - 2T\gamma\bar{w}_0 \right) \\
-\sigma_0^2 \left( \frac{1}{6} (T + 1) (T + 2) (T + 9\gamma + 9\bar{w}_0 - T\gamma - T\bar{w}_0 - 6\gamma\bar{w}_0 + T\gamma\bar{w}_0 - 12) \right) \\
-\sigma_0^2 \left( \frac{\gamma T + 1 (\gamma \bar{w}_0 - 1)}{\gamma^2 (1 - \gamma)^2} + \frac{\gamma (\gamma \bar{w}_0 - 1) (T + 2\gamma - T - 3)}{(\gamma - 1)^2} \right)
\]

Using these, we obtain
\[
\lim_{N \to \infty} N^{-1} \sum_{i=1}^{N} E \left( \Delta \tilde{y}_{i-1}^t \Phi_i \right) \\
= \lim_{N \to \infty} N^{-1} \sum_{i=1}^{N} \left( A_{ii} + A_{2i}^{(1)}(\bar{w}_0) + A_{2i}^{(2)}(\bar{w}_0) + A_{2i}^{(3)}(\bar{w}_0) \right) = 0.
\]

To prove (35), first note that \( E(\Delta W_i \Phi_i) \) is a \((T + 3)\) dimensional vector having all zeros, except for the \((T + 2)\)th entry, given by \( E(\Delta \tilde{y}_{i-1}^t \Phi_i) \). We have
\[
\delta_i = E(\vartheta^t r_i \Delta \tilde{y}_{i-1}^t \vartheta) = T \sum_{s=1}^{T-1} (T - s) E(\Delta y_{is} v_{i1}) + \sum_{s=1}^{T-1} \sum_{t=2}^{T} (T - t + 1)(T - s) E(\Delta y_{is} \Delta u_{it})
\]
\[
= T \sum_{s=1}^{T-1} (T - s) E(\Delta y_{is} v_{i1}) + \sum_{s=1}^{T-1} \sum_{t=1}^{T-1} (T - t + 1)(T - s) E(\Delta y_{is} \Delta u_{it})
\]

which can be written as
\[
\delta_i = T(T - 1) E(\Delta y_{i1} v_{i1}) + T \sum_{s=2}^{T-1} (T - s) E(\Delta y_{is} v_{i1}) + \sum_{s=1}^{T-1} \sum_{t=1}^{T-1} (T - t + 1)(T - s) E(\Delta y_{is} \Delta u_{it})
\]
\[
+ \sum_{s=1}^{T-1} (T - s + 1)(T - s) E(\Delta y_{is} \Delta u_{is}) + \sum_{s=1}^{T-1} (T - s)^2 E(\Delta y_{is} \Delta u_{is+1})
\]

Finally, we have
\[
\bar{\delta} = \lim_{N \to \infty} N^{-1} \sum_{i=1}^{N} \delta_i = T(T - 1)\bar{w}_0 + (\gamma \bar{w}_0 - 1) \sum_{s=2}^{T-1} (T - s) \gamma^{s-2}
\]
\[
-\sigma_0^2 (1 - \gamma)^2 \sum_{s=1}^{T-1} \sum_{t=1}^{T-1} (T - t + 1)(T - s) \gamma^{s-t-1} + \sigma_0^2 (2 - \gamma) \sum_{s=1}^{T-1} (T - s + 1)(T - s) - \sigma_0^2 \sum_{s=1}^{T-1} (T - s)^2.
\]
Second derivatives

Let us define the second derivatives of the pseudo log likelihood function (11) as follows:

\[
A_N (\theta) = -\frac{1}{N} \frac{\partial^2 \ell_p (\theta)}{\partial \theta \partial \theta'} = \begin{bmatrix}
A_{N,11} (\theta) & A_{N,12} (\theta) & A_{N,13} (\theta) \\
A'_{N,12} (\theta) & A_{N,22} (\theta) & A_{N,23} (\theta) \\
A'_{N,13} (\theta) & A'_{N,23} (\theta) & A_{N,33} (\theta)
\end{bmatrix}
\]  

(40)

where\(^{16}\)

\[
A_{N,11} (\theta) = -\frac{1}{N} \frac{\partial^2 \ell_p (\theta)}{\partial \varphi \partial \varphi'} = \frac{1}{\sigma^2} \frac{1}{N} \sum_{i=1}^{N} \Delta W'_i \Omega (\omega)^{-1} \Delta W_i,
\]

\[
A_{N,22} (\theta) = -\frac{1}{N} \frac{\partial^2 \ell_p (\theta)}{\partial \omega \partial \omega'} = -\frac{T^2}{2 g (\omega)} + \frac{T}{\sigma^2 g (\omega)} \frac{1}{N} \sum_{i=1}^{N} r'_i \Phi r_i,
\]

\[
A_{N,33} (\theta) = -\frac{1}{N} \frac{\partial^2 \ell_p (\theta)}{\partial (\sigma^2)^2} = -\frac{1}{2} \frac{1}{N} \sum_{i=1}^{N} \Delta W'_i \Phi r_i,
\]

\[
A_{N,12} (\theta) = -\frac{1}{N} \frac{\partial^2 \ell_p (\theta)}{\partial \varphi \partial \omega} = \frac{1}{\sigma^2} \frac{1}{N} \sum_{i=1}^{N} \Delta W'_i \Phi r_i,
\]

\[
A_{N,13} (\theta) = -\frac{1}{N} \frac{\partial^2 \ell_p (\theta)}{\partial \varphi \partial \sigma^2} = \frac{1}{2} \frac{1}{N} \sum_{i=1}^{N} \Delta W'_i \Phi r_i,
\]

\[
A_{N,23} (\theta) = -\frac{1}{N} \frac{\partial^2 \ell_p (\theta)}{\partial \omega \partial \sigma^2} = \frac{1}{2} \frac{1}{N} \sum_{i=1}^{N} \Delta W'_i \Phi r_i.
\]

We now derive \( \text{plim}_{N \to \infty} A_N (\theta) = \Lambda^* \). First, note that \( \Omega (\omega_i) \) can be written as \( \Omega (\omega_i) = \Omega (\omega_*) + \Delta (\omega_i - \omega_*) \) where \( \Delta (\omega_i - \omega_*) \) is a matrix whose (1,1) element is \( \omega_i - \omega_* \) and zeros otherwise. Then, since \( r'_i \Phi r_i \) and \( r'_i \Omega (\omega_i)^{-1} r_i \) are independent across \( i \), with mean \( T \sigma^2 g (\omega_i) \) and \( T \sigma^2 \), respectively, we have (recall from Assumption 5 that \( \lim_{N \to \infty} N^{-1} \sum_{i=1}^{N} \sigma^2_i \omega_i = \bar{\sigma}^2_0 \omega_0 \))

\[
\lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} E (r'_i \Phi r_i) = T \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} \sigma^2 i [1 + T (\omega_i - 1)] = T \sigma^2_0 [1 + T (\bar{\omega} - 1)] = T \sigma^2_0 g (\omega_*) \quad (41)
\]

\[
\lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} E \left( r'_i \Omega (\omega_*)^{-1} r_i \right) = \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} \sigma^2_i \text{tr} \left( \Omega (\omega_*)^{-1} \Omega (\omega_i) \right)
\]

\[
= \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} \sigma^2_i \left[ T + \text{tr} \left( \Omega (\omega_*)^{-1} \Delta (\omega_i - \omega_*) \right) \right]
\]

\[
= T \sigma^2_0 \left( 1 - \frac{T (\omega_* - 1) + (\bar{\omega} - \omega_*)}{g (\omega_0)} \right) = T \sigma^2_0. \quad (42)
\]

\(^{16}\)See also Hsiao, Pesaran, and Tahmiscioğlu (2002).
Then, using these and Lemma A1, the matrix $A^*$ is given by

$$A^* = \begin{pmatrix}
    \text{plim}_{N \to \infty} \frac{1}{N \sigma^2} \sum_{i=1}^{N} \Delta W'_i \Omega (\omega_*)^{-1} \Delta W_i & \text{plim}_{N \to \infty} \frac{1}{Ng(\omega)^2} \sum_{i=1}^{N} \Delta W'_i \Phi r_i & 0 \\
    \text{plim}_{N \to \infty} \frac{1}{Ng(\omega)^2} \sum_{i=1}^{N} r'_i \Phi \Delta W_i & \frac{T^2}{2g(\omega)^2} & \frac{T}{2g(\omega)\sigma^2} \\
    0 & \frac{T}{2g(\omega)\sigma^2} & \frac{T}{2(\sigma^2)^4}
\end{pmatrix}.$$

**Lemma A2** Let $b_N (\theta_*) = \left( 1/\sqrt{N} \right) \partial \ell_p (\theta_*) / \partial \theta$, where $\ell_p (\theta)$ is given by (11), and $\theta_* = (\varphi_*, \omega_*, \sigma^2_*)'$ is the vector of pseudo-true values. Then as $N$ tends to infinity and for fixed $T$, we have

$$b_N (\theta_*) \to N(0, B^*). \quad (43)$$

**Proof.** Note that $b^*_N$ can be written as

$$\frac{1}{\sqrt{N}} \frac{\partial \ell_p (\theta)}{\partial \theta} \bigg|_{\theta=\theta_*} = \frac{1}{\sqrt{N}} \left( \sum_{i=1}^{N} \Delta W'_i \Omega (\omega_*)^{-1} \Delta W_i \right) = \frac{1}{\sqrt{N}} \left( \sum_{i=1}^{N} \Delta W'_i \Omega (\omega_*)^{-1} \Delta W_i \right) \cdot \frac{1}{\sigma^2} \frac{1}{\sqrt{N}} \left( \sum_{i=1}^{N} \Delta W'_i \Phi r_i \right),$$

where

$$\xi_i = r'_i \Phi r_i - T \sigma^2 g(\omega_*) \quad \text{and} \quad \zeta_i = r'_i \Omega (\omega_*)^{-1} r_i - T \sigma^2_*.$$

By Lemma A1, $\lim_{N \to \infty} N^{-1} \sum_{i=1}^{N} E \left( \Delta W_i' \Omega (\omega_*)^{-1} \Delta W_i \right)$ has zero mean. Also, from (41) and (42), we have $\lim_{N \to \infty} N^{-1} \sum_{i=1}^{N} E \left( \xi_i \right) = 0$ and $\lim_{N \to \infty} N^{-1} \sum_{i=1}^{N} E \left( \zeta_i \right) = 0$. For the variance, since cross-sectional units are mutually independent, we have

$$B^*_{11} = \lim_{N \to \infty} \frac{1}{N} \frac{1}{\sigma^2} \sum_{i=1}^{N} E \left( \sum_{i=1}^{N} \Delta W_i' \Omega (\omega_*)^{-1} \Delta W_i \right) = \lim_{N \to \infty} \frac{1}{N} \frac{1}{\sigma^4} \sum_{i=1}^{N} \sum_{i=1}^{N} E \left( \Delta W_i' \Omega (\omega_*)^{-1} \Delta W_i \right). \quad (44)$$

Again, using (41) and (42) and recalling that $\lim_{N \to \infty} N^{-1} \sum_{i=1}^{N} E(\xi_i) = 0$, we have

$$B^*_{22} = \lim_{N \to \infty} \frac{1}{4g(\omega)^2 \sigma^4} E \left[ \frac{1}{N} \sum_{i=1}^{N} \sum_{i=1}^{N} \xi_i^2 \right] = \lim_{N \to \infty} \frac{1}{4g(\omega)^2 \sigma^4} E \left[ \frac{1}{N} \sum_{i=1}^{N} \left( r'_i \Phi r_i - T g(\omega_*) \sigma^2_* \right)^2 \right] = \lim_{N \to \infty} \frac{1}{4g(\omega)^2 \sigma^4} E \left[ \frac{1}{N} \sum_{i=1}^{N} \left( r'_i \Phi r_i \right)^2 - 2T g(\omega_*) \sigma^2_* \sum_{i=1}^{N} (r'_i \Phi r_i) + NT^2 g(\omega)^2 \sigma^4_* \right] = \frac{T^2}{4g(\omega)^2 \sigma^4} \lim_{N \to \infty} E \left[ \frac{1}{N} \sum_{i=1}^{N} \left( r'_i \Phi r_i \right)^2 - g(\omega)^2 \sigma^4_* \right]. \quad (45)$$
Similarly
\[
B_{33}^* = \lim_{N \to \infty} \frac{1}{4N (\sigma^2_*)^2} E \left[ \sum_{i=1}^{N} \xi_i^2 \right] = \lim_{N \to \infty} \frac{1}{4N (\sigma^2_*)^2} \left\{ E \left[ \sum_{i=1}^{N} \left( r'_i \Omega (\omega_*)^{-1} r_i \right)^2 \right] - NT^2 \sigma^4_* \right\}
\]
\[
= \frac{T^2}{4 \sigma^6_*} \lim_{N \to \infty} E \left[ \frac{1}{N} \sum_{i=1}^{N} \left( \frac{r'_i \Omega (\omega_*)^{-1} r_i}{T} \right)^2 - \sigma^4_* \right].
\] (46)

The off-diagonal elements of \( B^* \) are (noting that \( \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} E \left( \Delta W'_i \Omega (\omega_*)^{-1} r_i \right) = 0 \) and \( \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} E (\xi_i) = 0 \)):

\[
B_{21}^* = \lim_{N \to \infty} \frac{1}{2 \sigma^4_* g (\omega_*)^2} E \left[ \frac{1}{N} \sum_{i=1}^{N} \xi_i r'_i \Omega (\omega_*)^{-1} \Delta W_i \right]
\]
\[
= \lim_{N \to \infty} \frac{1}{2 \sigma^4_* g (\omega_*)^2} E \left[ \frac{1}{N} \sum_{i=1}^{N} \left( r'_i \Omega (\omega_*)^{-1} \Delta W_i \right) \left( r'_i \Phi r_i - T g (\omega_*) \sigma^2_* \right) \right]
\]
\[
= \lim_{N \to \infty} \frac{1}{2 \sigma^4_* g (\omega_*)^2} E \left[ \frac{1}{N} \sum_{i=1}^{N} \left( r'_i \Omega (\omega_*)^{-1} \Delta W_i \right) \left( r'_i \Phi r_i \right) \right].
\] (47)

\[
B_{31}^* = \lim_{N \to \infty} \frac{1}{2 \sigma^4_*} E \left[ \frac{1}{N} \sum_{i=1}^{N} \left( r'_i \Omega (\omega_*)^{-1} \Delta W_i \right) \left( r'_i \Omega (\omega_*)^{-1} r_i \right) \right].
\] (48)

Similarly, using (41) and (42), we have

\[
B_{32}^* = \lim_{N \to \infty} \frac{1}{4 \sigma^6_* g (\omega_*)^2} E \left( \frac{1}{N} \sum_{i=1}^{N} \xi_i^2 \right)
\]
\[
= \lim_{N \to \infty} \frac{T^2}{4 \sigma^6_* g (\omega_*)^2} E \left[ \frac{1}{N} \sum_{i=1}^{N} \left( \frac{r'_i \Phi r_i}{T} - g (\omega_*) \sigma^2_* \right) \left( r'_i \Omega (\omega_*)^{-1} r_i - \sigma^2_* \right) \right]
\]
\[
= \lim_{N \to \infty} \frac{T^2}{4 \sigma^6_* g (\omega_*)^2} E \left[ \frac{1}{N} \sum_{i=1}^{N} \left( \frac{r'_i \Phi r_i}{T} \frac{r'_i \Omega (\omega_*)^{-1} r_i}{T} - g (\omega_*) \sigma^2_* \frac{r'_i \Omega (\omega_*)^{-1} r_i}{T} - \sigma^2_* \frac{r'_i \Phi r_i}{T} + g (\omega_*) \sigma^4_* \right) \right]
\]
\[
= \lim_{N \to \infty} \frac{T^2}{4 \sigma^6_* g (\omega_*)^2} E \left[ \frac{1}{N} \sum_{i=1}^{N} \left( \frac{r'_i \Phi r_i}{T} \frac{r'_i \Omega (\omega_*)^{-1} r_i}{T} - g (\omega_*) \sigma^4_* \right) \right].
\] (49)

For fixed \( T \), the elements inside the sum operator in expressions (44)-(49) are finite for all \( i \). Hence, (43) is established by applying the central limit theorem for independent and heterogeneous random variables (White, 2001).
B.2 Proof of Theorem 1

First note that equation (6) can be rewritten as

$$\eta_{i1} = E(\eta_{i1}|\Delta x_i) + [\eta_{i1} - E(\eta_{i1}|\Delta x_i)] = E(\eta_{i1}|\Delta x_i) + \zeta_{i1}, \quad (50)$$

where \( \zeta_{i1} = \eta_{i1} - E(\eta_{i1}|\Delta x_i) \). Also, we have

$$E(\eta_{i1}|\Delta x_i) = \gamma^m E(\Delta y_{i,-m+1}|\Delta x_i) + \beta \Delta x_{i1} + \beta \sum_{j=1}^{m-1} \gamma^j E(\Delta x_{i,1-j}|\Delta x_i). \quad (51)$$

Using either (3) or (4) we have

$$\Delta x_{it} = \phi + \sum_{j=0}^{\infty} \tilde{d}_j \varepsilon_{i,t-j}, \quad (52)$$

with \( \tilde{d}_j = d_j \) under (4), \( \tilde{d}_j = a_j - a_{j-1} \) under (3), and \( \tilde{d}_0 = a_0 \). Hence, it is easily seen that under (52)

$$E(\Delta x_{i,1-j}|\Delta x_i) = b_j + \pi'_j \Delta x_i, \quad (j = 1, ..., m - 1) \quad (53)$$

where \( b_j \) and \( \pi_j \) do not depend on \( i \). Using Assumption 3 and (53) in (51), we have

$$E(\eta_{i1}|\Delta x_i) = \gamma^m (b_m + \pi'_m \Delta x_i) + \beta \Delta x_{i1} + \beta \sum_{j=1}^{m-1} \gamma^j (b_j + \pi'_j \Delta x_i)$$

$$= \left( \gamma^m b_m + \beta \sum_{j=1}^{m-1} \gamma^j b_j \right) + \left( \pi_m + \beta e_1 + \beta \sum_{j=1}^{m-1} \gamma^j \pi_j \right)' \Delta x_i$$

$$= b + \pi' \Delta x_i \quad (54)$$

where \( e_1 = (1, 0, ..., 0)' \), \( b \) is a constant, and \( \pi \) is a \( T \)-dimensional vector of parameters. Then, using (5), (50) and (54), \( \Delta y_{i1} \) can be written as

$$\Delta y_{i1} = \eta_{i1} + \sum_{j=0}^{m-1} \gamma^j \Delta u_{i,1-j} = E(\eta_i|\Delta x_i) + \zeta_{i1} + \sum_{j=0}^{m-1} \gamma^j \Delta u_{i,1-j}$$

$$= b + \pi' \Delta x_i + v_{i1},$$

where \( v_{i1} = \zeta_{i1} + \sum_{j=0}^{m-1} \gamma^j \Delta u_{i,1-j} \). In the above equation, \( v_{i1} \) has zero mean and variance \( E(v_{i1}^2) = \omega_i \sigma_i^2 \).
B.3 Proof of Theorem 2

To simplify the derivation and better understand the model, we consider an alternative expression of the model proposed by Grassetti (2011). By pre-multiplying (9) by the \(T \times T\) accumulation matrix,

\[
L_T = \begin{pmatrix}
    1 & 0 & \ldots & 0 \\
    1 & 1 & \ldots & 0 \\
    \vdots & \vdots & \ddots & \vdots \\
    1 & 1 & \ldots & 1
\end{pmatrix},
\]

we obtain

\[
\begin{pmatrix}
    y_{i1} - y_{i0} \\
    y_{i2} - y_{i0} \\
    \vdots \\
    y_{iT} - y_{i0}
\end{pmatrix} =
\begin{pmatrix}
    1 & \Delta x'_i & 0 & 0 \\
    1 & \Delta x'_i & y_{i1} - y_{i0} & x_{i2} - x_{i1} \\
    \vdots & \vdots & \vdots & \vdots \\
    1 & \Delta x'_i & y_{i,T-1} - y_{i0} & x_{iT} - x_{i1}
\end{pmatrix} \varphi + \begin{pmatrix}
    \xi_i + u_{i1} \\
    \xi_i + u_{i2} \\
    \vdots \\
    \xi_i + u_{iT}
\end{pmatrix},
\]

which can be written more compactly as

\[
\dot{y}_i = \dot{W}_i \varphi + \dot{r}_i,
\]

where

\[v_{i1} = u_{i1} + (v_{i1} - u_{i1}) = u_{i1} + \xi_i, \quad \text{and} \quad \dot{r}_i = \varphi + \xi_i + u_{i1}.
\]

Since \(L_T\) does not depend on any parameters, then the likelihood functions for (9) and (55) are identical, also noting that the Jacobian of the transformation \(L_T\), given by \(|L_T| = 1\). Hence, the ML estimators based on the transformed ML estimator for (9) and (55) will be identical.

The th row of (55) can be written as

\[
(y_{it} - y_{i0}) = \beta + \Delta x'_i + (y_{i,t-1} - y_{i0})\gamma + (x_{it} - x_{i1})\beta + \xi_i + u_{it}.
\]

Also, from the definition of \(\xi_i\),

\[
\xi_i = v_{i1} - u_{i1} = \left(\varsigma_{i1} + \sum_{j=0}^{m-1} \gamma^j \Delta u_{i,1-j}\right) - u_{i1} = \varsigma_{i1} - (1 - \gamma)u_{i0} - (1 - \gamma) \sum_{j=1}^{m-2} \gamma^j u_{i,-j} - \gamma^{m-1} u_{i,-m+1}
\]

where \(\varsigma_{i1} = \eta_{i1} - E(\Delta y_{i1}|\Delta x_i), \eta_{i1} = E(\Delta y_{i1}|\Delta y_{i,m+1}, \Delta x_{i1}, \Delta x_{i0}, \ldots)\). Note that \(var(\xi_i) = \sigma_{\xi_i}^2 = \sigma_i^2(\omega_i - 1)\). Using Assumption 5, we have \(\tilde{\sigma}_0^2 = \lim_{\gamma \to \infty} \frac{1}{N} \sum_{i=1}^N \sigma_{\xi_i}^2 = \lim_{\gamma \to \infty} \frac{1}{N} \sum_{i=1}^N (\omega_i - 1) \sigma_i^2 = \bar{\sigma}_0^2(\bar{\omega}_0 - 1)\). Although (55) looks like the standard random effect model, it is not the case since the regressor \((y_{i,t-1} - y_{i0})\) and new individual effects \(\xi_i\) are correlated.
For some $\sigma^2$ and $\sigma^2_\xi = \sigma^2 (\omega - 1)$, define

\[
\begin{align*}
V_T &= E (\tilde{r}_i \tilde{r}_i') = \sigma^2 I_T + \sigma^2_\xi \ell_T \ell_T', \quad V_T^{-1} = \frac{1}{\sigma^2} \left[ I_T - (1 - \psi) \frac{1}{T} \ell_T \ell_T' \right], \\
Q_T &= I_T - \frac{1}{T} \ell_T \ell_T', \quad \psi = \frac{\sigma^2}{\sigma^2 + T \sigma^2_\xi} = \frac{1}{1 + T (\omega - 1)}, \quad 1 - \psi = \frac{T (\omega - 1)}{1 + T (\omega - 1)}.
\end{align*}
\]

Then, by using $|V_T| = \sigma^2 (T^{-1}) (\sigma^2 + T \sigma^2_\xi) = \sigma^2 T [1 + T (\omega - 1)]$, the alternative expression for the pseudo log-likelihood function under homoskedasticity can be written as

\[
\ell_{RE} (\theta) = -\frac{NT}{2} \ln (2\pi) - \frac{N}{2} \ln |V_T| - \frac{1}{2} \sum_{i=1}^N \tilde{r}'_i V_T^{-1} \tilde{r}_i \\
\propto -\frac{NT}{2} \ln \sigma^2 - \frac{N}{2} \ln [1 + T (\omega - 1)] - \frac{1}{2\sigma^2} \sum_{i=1}^N (\tilde{y}_i - \tilde{W}_i \varphi)' Q_T (\tilde{y}_i - \tilde{W}_i \varphi) \\
- \frac{1}{2\sigma^2 T [1 + T (\omega - 1)]} \sum_{i=1}^N (\tilde{y}_i - \tilde{W}_i \varphi)' \ell_T \ell_T' (\tilde{y}_i - \tilde{W}_i \varphi)
\]

where $\theta = (\varphi', \omega, \sigma^2)'$. Under heteroskedastic errors, the pseudo-true value of $\theta$ denoted by $\theta_* = (\varphi'_*, \omega_*, \sigma^2_*)'$, is the solution of $\lim_{N \to \infty} N^{-1} E [\partial \ell_{RE} (\theta_*) / \partial \theta] = 0$, and can be written as

\[
\begin{align*}
\varphi_* &= \lim_{N \to \infty} N^{-1} \sum_{i=1}^N E \left( \tilde{W}'_i V_T^{-1}_T \tilde{W}_i \right)^{-1} \lim_{N \to \infty} N^{-1} \sum_{i=1}^N E \left( \tilde{W}'_i V_T^{-1}_T \tilde{y}_i \right), \\
1 + T (\omega_* - 1) &= \frac{1}{\sigma^2_*} \lim_{N \to \infty} \frac{1}{NT} \sum_{i=1}^N E \left[ (\tilde{y}_i - \tilde{W}_i \varphi_*)' \ell_T \ell_T' (\tilde{y}_i - \tilde{W}_i \varphi_*) \right], \\
\sigma^2_* &= \lim_{N \to \infty} N (T - 1) \sum_{i=1}^N E \left[ (\tilde{y}_i - \tilde{W}_i \varphi_*)' Q_T (\tilde{y}_i - \tilde{W}_i \varphi_*) \right],
\end{align*}
\]

where $V_{T_*} = \sigma^2_* I_T + \sigma^2_*(\omega_* - 1) \ell_T \ell_T'$. Substituting $\sigma^2_*$ into the expression of $\sigma^2_*$, we have

\[
1 + T (\omega_* - 1) = \frac{\lim_{N \to \infty} \frac{1}{NT} \sum_{i=1}^N E \left[ (\tilde{y}_i - \tilde{W}_i \varphi_*)' \ell_T \ell_T' (\tilde{y}_i - \tilde{W}_i \varphi_*) \right]}{\lim_{N \to \infty} \frac{1}{N(T - 1)} \sum_{i=1}^N E \left[ (\tilde{y}_i - \tilde{W}_i \varphi_*)' Q_T (\tilde{y}_i - \tilde{W}_i \varphi_*) \right]}.
\]

The expectations in the above first order conditions are taken with respect to the true heteroskedastic model. To derive these expectations we first note that

\[
\hat{y}_i - \hat{W}_i \varphi_* = \hat{r}_i - \hat{W}_i (\varphi_* - \varphi_0),
\]
and obtain

\[
\frac{1}{T} E \left[ (\tilde{y}_i - \tilde{W}_i \varphi^*)' \nu_T \nu_T' (\tilde{y}_i - \tilde{W}_i \varphi^*) \right] = \sigma_i^2 \left[ 1 + T(\omega_i - 1) \right] - 2(\varphi^* - \varphi_0)' E \left( T^{-1} \tilde{W}_i' \nu_T \nu_T' \tilde{r}_i \right) + (\varphi^* - \varphi_0)' E \left( T^{-1} \tilde{W}_i' \nu_T \nu_T' \tilde{W}_i \right) (\varphi^* - \varphi_0),
\]

and

\[
\frac{1}{T-1} E \left[ (\tilde{y}_i - \tilde{W}_i \varphi^*)' Q_T (\tilde{y}_i - \tilde{W}_i \varphi^*) \right] = \sigma_i^2 - 2(\varphi^* - \varphi_0)' E \left( \frac{1}{T-1} \tilde{W}_i' Q_T \tilde{r}_i \right) + (\varphi^* - \varphi_0)' E \left( \frac{1}{T-1} \tilde{W}_i' Q_T \tilde{W}_i \right) (\varphi^* - \varphi_0).
\]

Using the above results in (59) we obtain

\[
\omega^* - \hat{\omega}_0 = -\frac{1 + T(\omega^* - 1)}{\sigma_i^2 (T-1)} (\varphi^* - \varphi_0)' \lim_{N \to \infty} N^{-1} \sum_{i=1}^N E \left[ T^{-1} \tilde{W}_i' (I_T - h_a \nu_T \nu_T') \tilde{W}_i \right] (\varphi^* - \varphi_0) + \frac{2}{\sigma_i^2 (T-1)} (\varphi^* - \varphi_0)' \lim_{N \to \infty} N^{-1} \sum_{i=1}^N E \left[ T^{-1} \tilde{W}_i' (I_T - h_a \nu_T \nu_T') \tilde{r}_i \right] \quad (60)
\]

where \(h_a = \omega^* / [1 + T(\omega^* - 1)]\). Similarly, using the first order condition (57) we also have

\[
\left[ \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^N E \left( T^{-1} \tilde{W}_i' V_{T*}^{-1} \tilde{W}_i \right) \right] (\varphi^* - \varphi_0) = \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^N E \left( T^{-1} \tilde{W}_i' V_{T*}^{-1} \tilde{r}_i \right) = \frac{1}{\sigma_i^2} \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^N E \left[ T^{-1} \tilde{W}_i' (I_T - h_b \nu_T \nu_T') \tilde{r}_i \right] \quad (61)
\]

where \(h_b = (\omega^* - 1) / [1 + T(\omega^* - 1)]\). Since the regressors are assumed to be exogenous then (recall also that \(\tilde{r}_i = \nu_T \tilde{\xi}_i + u_i\))

\[
E \left[ \tilde{W}_i' \left( I_T - \frac{\omega^* - 1}{1 + T(\omega^* - 1)} \nu_T \nu_T' \right) \tilde{r}_i \right] = e_3 \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^N E \left[ \tilde{y}_{i,-1}' \left( I_T - h_b \nu_T \nu_T' \right) (\nu_T \tilde{\xi}_i + u_i) \right], \quad (62)
\]

where \(\tilde{y}_{i,-1} = (0, y_{i1} - y_{i0}, ..., y_{iT-1} - y_{i0})'\), and \(e_3 = (0, 0, 0_T^{'}, 1, 0)'\).

To evaluate the expectations in the above formulas, we first derive some preliminary results. From
the model (56), for \( t = 2, \ldots, T \), we have

\[
\hat{y}_{it} = y_{it} - y_{i0} = (1 + \gamma_0 + \ldots + \gamma_0^{t-2}) \left( b_0 + \pi_0' \Delta x_i \right) + \gamma_0^{t-1} (y_{i1} - y_{i0}) + \beta_0 \left( \sum_{j=0}^{t-2} \gamma_0^j (x_{i,t-j} - x_{i1}) \right) + (1 + \gamma_0 + \ldots + \gamma_0^{t-2}) \xi_i + \sum_{j=0}^{t-2} \gamma_0^j u_{i,t-j}.
\]

Then, using (63) and (64), we have

\[
E \left[ (y_{it} - y_{i0}) u_{i,s} \right] = E \left[ (u_{it} + \gamma_0 u_{i,t-1} + \ldots + \gamma_0^{t-1} u_{i1}) u_{i,s} \right] = \begin{cases} \sigma_\alpha^2 \gamma_0^{t-s} & t \geq s \\ 0 & t < s \end{cases}.
\]

Also, we have

\[
E [\xi_i (y_{it} - y_{i0})] = \left( \frac{1 - \gamma_0^T}{1 - \gamma_0} \right) \sigma_\xi^2 \xi_i = \left( \frac{1 - \gamma_0^T}{1 - \gamma_0} \right) \sigma_\alpha^2 (\omega_{i0} - 1)
\]

(64)

Then, using (63) and (64), we have

\[
E (\hat{y}_{i,-1}^t \nu_T \nu_T u_i) = \nu_T E (u_i \hat{y}_{i,-1}^t) \nu_T = \left( \frac{\sigma_\alpha^2}{1 - \gamma_0} \right) \left[ T - \frac{1 - \gamma_0^T}{1 - \gamma_0} \right] = T \phi_0 \sigma_\alpha^2,
\]

\[
E (\xi_i \hat{y}_{i,-1}^t \nu_T) = \sum_{t=1}^{T-1} E [\xi_i (y_{it} - y_{i0})] = \left( \frac{\sigma_\xi^2}{1 - \gamma_0} \right) \sum_{t=1}^{T-1} (1 - \gamma_0^t) = T \phi_0 \sigma_\alpha^2 (\omega_{i0} - 1)
\]

where

\[
\phi_0 = \frac{1}{1 - \gamma_0} \left( 1 - \frac{1}{T} \frac{1 - \gamma_0^T}{1 - \gamma_0} \right).
\]

Using the above results it now readily follows that

\[
\lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^N E \left[ \hat{y}_{i,-1}^t (I_T - h \nu_T \nu_T) (\nu_T \xi_i + u_i) \right] = T \phi_0 \sigma_\alpha^2 \left( 1 - h T \right) (\bar{\omega}_0 - 1) - h \right].
\]

Using this result with \( h = h_0 = (\omega_s - 1) / [1 + T (\omega_s - 1)] \) in (62) and then in (61) yields

\[
\left[ \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^N E \left( T^{-1} \hat{W}_i \hat{V}_T^{-1} \hat{W}_i \right) \right] (\varphi_* - \varphi_0) = e_3 \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^N E \left( T^{-1} \hat{y}_{i,-1}^t \hat{V}_T^{-1} \hat{r}_i \right) = e_3 \frac{-\phi_0 \sigma_\alpha^2}{\sigma_*^2} \frac{(\omega_s - \bar{\omega}_0)}{1 + T (\omega_s - 1)}.
\]

(65)
Similarly, 

\[
\lim_{N \to \infty} N^{-1} \sum_{i=1}^{N} E \left[ T^{-1} \hat{W}_i \left( I_T - h_a \mathbf{t}_T \mathbf{t}_T' \right) \hat{r}_i \right] = -\mathbf{e}_3 \frac{\phi_0 \bar{\sigma}_0^2 \left[ (T - 1) (\bar{\omega}_0 - 1) + \omega_* \right]}{1 + T (\omega_* - 1)},
\]

and hence using (60) we have

\[
\omega_* - \bar{\omega}_0 = -\frac{1 + T (\omega_* - 1)}{\bar{\sigma}_0^2 (T - 1)} (\varphi_* - \varphi_0)' \lim_{N \to \infty} N^{-1} \sum_{i=1}^{N} E \left[ T^{-1} \hat{W}_i \left( I_T - h_a \mathbf{t}_T \mathbf{t}_T' \right) \hat{W}_i \right] (\varphi_* - \varphi_0)
\]

\[-\frac{2\phi_0 [(T - 1) (\bar{\omega}_0 - 1) + \omega_*]}{(T - 1)} (\varphi_* - \varphi_0)' \mathbf{e}_3 \]  

(66)

Furthermore, we note that the following limits exist

\[
\mathbf{A} = \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} E \left( T^{-1} \hat{W}_i \hat{W}_i \right) \]  

\[
\mathbf{B} = \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} E \left( T^{-1} \hat{W}_i \mathbf{t}_T \mathbf{t}_T' \hat{W}_i \right),
\]

and

\[
\lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} E \left( T^{-1} \hat{W}_i \mathbf{V}_{T_*}^{-1} \hat{W}_i \right) = \frac{1}{\bar{\sigma}_0^2} \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} E \left[ T^{-1} \hat{W}_i \left( I_T - h_b \mathbf{t}_T \mathbf{t}_T' \right) \hat{W}_i \right]
\]

\[= \frac{1}{\bar{\sigma}_0^2} \left[ \mathbf{A} - \varfrac{\omega_* - 1}{1 + T (\omega_* - 1)} \mathbf{B} \right],
\]

which is a positive definite matrix. Using these result in (65) and (66) we have

\[
\varphi_* - \varphi_0 = -\phi_0 \bar{\sigma}_0^2 \frac{(\omega_* - \bar{\omega}_0)}{1 + T (\omega_* - 1)} \left[ \mathbf{A} - \frac{\omega_* - 1}{1 + T (\omega_* - 1)} \mathbf{B} \right]^{-1} \mathbf{e}_3.
\]

(67)

and

\[
(\omega_* - \bar{\omega}_0) = -\frac{1 + T (\omega_* - 1)}{(T - 1) \bar{\sigma}_0^2} (\varphi_* - \varphi_0)' \left[ \mathbf{A} - \frac{\omega_* - 1}{1 + T (\omega_* - 1)} \mathbf{B} \right] (\varphi_* - \varphi_0)
\]

\[-\varfrac{2\phi_0 [(T - 1) (\bar{\omega}_0 - 1) + \omega_*]}{(T - 1)} (\varphi_* - \varphi_0)' \mathbf{e}_3.
\]

Substituting \(\varphi_* - \varphi_0\) from (67) in the above and after some algebra we have

\[
\left\{ 1 - \frac{2\kappa_2 \phi_0^2 \bar{\sigma}_0^2 [(T - 1) (\bar{\omega}_0 - 1) + \omega_*]}{(T - 1) [1 + T (\omega_* - 1)]} \right\} (\omega_* - \bar{\omega}_0) = \frac{-\kappa_1 \phi_0^2 \bar{\sigma}_0^2}{(T - 1) [1 + T (\omega_* - 1)]} (\omega_* - \bar{\omega}_0)^2.
\]

(68)
However, for a finite \( T \) the first order equations. Using this result in (68) and (69) it also follows that

\[
\kappa_1 = e'_3 \left[ A - \frac{\omega_* - 1}{1 + T (\omega_* - 1)} B \right]^{-1} \quad \kappa_2 = e'_3 \left[ A - \frac{\omega_* - 1}{1 + T (\omega_* - 1)} B \right]^{-1} e_3.
\]

Also, using (58)

\[
\sigma_*^2 = \lim_{N \to \infty} \frac{1}{N(T-1)} \sum_{i=1}^{N} \mathbb{E} \left[ (\hat{y}_i - \hat{W}_i \phi)^\prime Q_T (\hat{y}_i - \hat{W}_i \phi) \right] = \overline{\sigma}_0^2 + \frac{2 \phi_0 \overline{\sigma}_0^2}{T-1} (\phi_\star - \phi_0)' e_3 + \left( \frac{T}{T-1} \right) (\phi_\star - \phi_0)' C (\phi_\star - \phi_0)
\]

where \( C = A - T^{-1} B \).

It is clear that for a finite \( T \) all the terms in (68) are finite and as required \( \omega_* = \omega_0 \) is a solution of the first order equations. Using this result in (68) and (69) it also follows that \( \phi_\star = \phi_0 \) and \( \sigma_*^2 = \sigma_0^2 \).

However, for a finite \( T \) this solution is not unique and (68) has another solution given implicitly by

\[
\omega_* = \omega_0 - \frac{(T-1) [1 + T (\omega_* - 1)] - 2 \phi_0 \overline{\sigma}_0^2 [(T-1) (\omega_0 - 1) + \omega_*] \kappa_2}{\phi_0^2 \overline{\sigma}_0^2 \kappa_1}.
\]

Under this solution \( \phi_* \neq \phi_0 \).

### B.4 Proof of Theorem 3

First, by applying the mean-value theorem to \( \left( 1/\sqrt{N} \right) \partial \ell_p (\theta) / \partial \theta \) around \( \hat{\theta} = \theta_* \), we have

\[
0 = \frac{1}{\sqrt{N}} \frac{\partial \ell_p (\theta_0)}{\partial \theta} = \frac{1}{\sqrt{N}} \frac{\partial \ell_p (\theta_*)}{\partial \theta} + \frac{1}{\sqrt{N}} \frac{\partial^2 \ell_p (\hat{\theta})}{\partial \theta^2} \sqrt{N} \left( \theta - \theta_* \right);
\]

where \( \hat{\theta} \) lies element-wise between the line segment joining \( \theta \) and \( \theta_* \). Rearranging, we have

\[
\sqrt{N} \left( \hat{\theta} - \theta_* \right) = \left[ - \frac{1}{N} \frac{\partial^2 \ell_p (\hat{\theta})}{\partial \theta^2} \right]^{-1} \frac{1}{\sqrt{N}} \frac{\partial \ell_p (\theta_*)}{\partial \theta} = A_N (\hat{\theta})^{-1} b_N (\theta_*)
\]

where \( A_N (\theta) \) is defined in (40). We demonstrate that \( A_N (\theta_*) - A_N (\hat{\theta}) \to^p 0 \) as \( N \to \infty \) and for fixed \( T \). First note that

\[
\mathbf{r}_i (\phi) = \mathbf{r}_i (\phi_\star) - \Delta \mathbf{W}_i (\phi - \phi_\star),
\]

\[
\mathbf{\Omega} (\omega)^{-1} = \frac{1}{g(\omega)} \Xi (\omega) = \mathbf{\Omega} (\omega_\star)^{-1} + \frac{g(\omega_\star) \Xi (\omega_\star) + [g(\omega_\star) - g(\omega)] \Xi (\omega_\star)}{g(\omega) g(\omega_\star)} = \mathbf{\Omega} (\omega_\star)^{-1} + \Lambda (\Delta \omega)
\]

40
where $\Delta \omega = \bar{\omega} - \omega_*$. Also, given consistency results, we have $\bar{\varphi} - \varphi_* \to^p 0$, $\Delta \omega = \bar{\omega} - \omega_* \to^p 0$, $\Lambda(\Delta \omega) \to^p 0$, $\sigma_*^2 - \bar{\sigma}^2 \to^p 0$, and $g(\bar{\omega}) - g(\omega_*) = T\Delta \omega \to^p 0$. Using these, we have

$$A_{N,11}(\theta) - A_{N,11}(\bar{\theta}) = \left(\frac{\sigma_*^2 - \bar{\sigma}^2}{\sigma_*^2 + \bar{\sigma}^2}\right) \frac{1}{N} \sum_{i=1}^{N} \Delta W_i' \Omega(\omega_*)^{-1} \Delta W_i + \frac{1}{\sigma^2} \frac{1}{N} \sum_{i=1}^{N} \Delta W_i' \Lambda(\Delta \omega) \Delta W_i \to^p 0,$$

$$A_{N,22}(\theta) - A_{N,22}(\bar{\theta}) = -\frac{T^2}{2} \left[ \frac{g(\omega_*)^2 - g(\bar{\omega})^2}{g(\bar{\omega})^2 g(\omega_*)^2} \right] + \left[ \frac{\sigma_*^2 g(\omega_*)^3 - \bar{\sigma}^2 g(\bar{\omega})^3}{\sigma_*^2 g(\omega_*)^3 + \bar{\sigma}^2 g(\bar{\omega})^3} \right] \frac{T}{N} \sum_{i=1}^{N} r_i(\varphi_*)' \Phi r_i(\varphi_*)$$
$$+ \frac{\sigma^2}{\sigma_*^2 g(\omega_*)^3} \frac{1}{N} \sum_{i=1}^{N} \left[ -2r_i(\varphi_*)' \Phi \Delta W_i(\bar{\varphi} - \varphi_*) + (\bar{\varphi} - \varphi_*)' \Delta W_i' \Phi \Delta W_i(\bar{\varphi} - \varphi_*) \right] \to^p 0,$$

$$A_{N,33}(\theta) - A_{N,33}(\bar{\theta}) = -\frac{T}{2} \left[ \frac{(\sigma_*^2)^2 - (\bar{\sigma}^2)^2}{(\sigma_*^2)^2 + (\sigma_*^2)^2} \right] + \left[ \frac{(\sigma_*^2)^3 - (\bar{\sigma}^2)^3}{(\sigma_*^2)^3 + (\sigma_*^2)^3} \right] \frac{1}{N} \sum_{i=1}^{N} r_i(\varphi_*)' \Omega(\omega_*)^{-1} r_i(\varphi_*)$$
$$+ \frac{1}{(\sigma_*^2)^3} \frac{1}{N} \sum_{i=1}^{N} r_i(\varphi_*)' \Lambda(\Delta \omega) r_i(\varphi_*)$$
$$+ \frac{1}{(\sigma_*^2)^3} \frac{1}{N} \sum_{i=1}^{N} \left[ -2r_i(\varphi_*)' \Omega(\omega_*)^{-1} \Delta W_i(\bar{\varphi} - \varphi_*) + (\bar{\varphi} - \varphi_*)' \Delta W_i' \Omega(\omega_*)^{-1} \Delta W_i(\bar{\varphi} - \varphi_*) \right] \to^p 0,$$

$$A_{N,12}(\theta) - A_{N,12}(\bar{\theta}) = \left[ \frac{\sigma_*^2 g(\omega_*)^2 - \bar{\sigma}^2 g(\bar{\omega})^2}{\sigma_*^2 g(\omega_*)^2 + \bar{\sigma}^2 g(\bar{\omega})^2} \right] \frac{1}{N} \sum_{i=1}^{N} \Delta W_i' \Phi r_i(\varphi_*)$$
$$- \frac{1}{\sigma^2 g(\bar{\omega})^2} \frac{1}{N} \sum_{i=1}^{N} \Delta W_i' \Phi \Delta W_i(\bar{\varphi} - \varphi_*) \to^p 0,$$
\[
A_{N,13}(\theta) - A_{N,13}(\tilde{\theta}) = \left[ \frac{(\sigma^2)^2 - (\bar{\sigma})^2}{(\bar{\sigma})^2(\sigma^2)^2} \right] \frac{1}{N} \sum_{i=1}^{N} \Delta W_i^\prime \Omega(\omega) r_i(\varphi) \\
\quad + \frac{1}{(\bar{\sigma})^2} \frac{1}{N} \sum_{i=1}^{N} \Delta W_i^\prime \Lambda(\Delta \omega) r_i(\varphi) \quad - \frac{1}{(\bar{\sigma})^2} \frac{1}{N} \sum_{i=1}^{N} \Delta W_i^\prime \Omega(\bar{\omega})^{-1} \Delta W_i (\bar{\varphi} - \varphi) \\
\quad \xrightarrow{p} 0.
\]

\[
A_{N,23}(\theta) - A_{N,23}(\tilde{\theta}) = \left[ \frac{(\sigma^2)^2 - (\bar{\sigma})^2}{(\bar{\sigma})^2(\sigma^2)^2} \right] \frac{1}{N} \sum_{i=1}^{N} r_i(\varphi) \Phi r_i(\varphi) \\
\quad + \frac{1}{2(\bar{\sigma})^2} \frac{1}{N} \sum_{i=1}^{N} \left[ -2r_i(\varphi) \Phi \Delta W_i (\bar{\varphi} - \varphi) \\
\quad + (\bar{\varphi} - \varphi) \Phi \Delta W_i (\bar{\varphi} - \varphi) \right] \xrightarrow{p} 0.
\]

Thus, \( A_N(\theta) - A_N(\tilde{\theta}) \xrightarrow{p} 0 \) as \( N \to \infty \) which in turn implies that \( A(\theta) - A_N(\tilde{\theta}) \xrightarrow{p} 0 \). Then by the Slutsky’s theorem

\[
\sqrt{N} (\tilde{\theta} - \theta) = A(\theta)^{-1} b_N(\theta) + o_p(1).
\]

Further, by Lemma A2, as \( N \to \infty \) and for a fixed \( T \) we have

\[
b_N(\theta) = \frac{1}{\sqrt{N}} \frac{\partial \ell_p(\theta)}{\partial \theta} \xrightarrow{d} N(0, B^\star),
\]

where the elements of \( B^\star \) are given in expressions (44)-(49). Hence, result (14) follows, and \( \tilde{\theta} \) is asymptotically normally distributed for a fixed \( T \), and as \( N \) tends to infinity.

Note: “DIF2” denotes Arellano and Bond type moment conditions: $E(y_{it,-2-l}\Delta u_{it}) = 0$ with $l = 0$ for $t = 2, l = 0, 1$ for $t = 3, ..., T$ and $E(x_{it,-l}\Delta u_{it}) = 0$ with $l = 0, 1$ for $t = 2, l = 0, 1, 2$ for $t = 3, ..., T$. One-step first-difference GMM estimator is computed by (20) with a suitable modification of $Z_i$. “SYS2” denotes Blundell and Bond type moment conditions: $E[y_{it,-1}(\alpha_i + u_{it})] = 0$ and $E[x_{it}(\alpha_i + u_{it})] = 0$ for $t = 2, ..., T$ in addition to the ones used in “DIF2”. One-step system GMM estimator is computed by (25) with a suitable modification of $Z_i$. The numbers of moment conditions of “DIF2” and “SYS2” are 18 and 26 when $T = 5$, 43 and 61 when $T = 10$ and 68 and 96 when $T = 15$. “-” denotes the cases where the GMM estimators are not computed since the number of moment conditions exceeds the sample size.

Anderson and Rubin test based on moment conditions "SYS2"

For the definition of "DIF2" and "SYS2", see notes to Table 1. “Anderson and Rubin test” denotes Anderson and Rubin test for GMM (Stock and Wright 2000)(eq. (30)). “Lagrange multiplier test” denotes Kleibergen’s(2005) LM test (eq. (31)). “Conditional likelihood ratio test” denotes the conditional likelihood ratio test of Moreira (2003)(extended by Kleibergen(2005)) (eq.(32)). “…” denotes the cases where the GMM estimators are not computed since the number of moment conditions exceeds the sample size.

Note: “DIF2” denotes Arellano and Bond type moment conditions $E(y_{it-2-1}u_{it}) = 0$ with $l = 0$ for $t = 2, l = 1$ for $t = 3, ..., T$. One-step first-difference GMM estimator is computed by (20) with a suitable modification of $\mathbf{Z}_i$ and $\mathbf{W}_i$. “SYS2” denotes Bond type moment conditions $E[\Delta y_{it-1} (u_t + u_{it})] = 0$ for $t = 2, ..., T$ in addition to the ones used in “DIF2”. One-step system GMM estimator is computed by (25), (26) and (29) with a suitable modification of $\mathbf{Z}_i$ and $\mathbf{W}_i$. The numbers of moment conditions of “DIF2” and “SYS2” are 7 and 11 when $T = 5$, 17 and 26 when $T = 10$, 27 and 41 when $T = 15$ and 37 and 56 when $T = 20$.
